ADVISORY COMMISSION ON  
INTERGOVERNMENTAL RELATIONS  
WASHINGTON, DC 20575  
MARCH 1982

**M-134**

# COMMISSION MEMBERS

## Private Citizens

Eugene Eidenberg, District of Columbia  
Robert B. Hawkins, Jr., California  
Mary Eleanor Wall, Illinois

## Members of the United States Senate

David Durenberger, Minnesota  
William V. Roth, Delaware  
James R. Sasser, Tennessee

## Members of the U.S. House of Representatives

Clarence J. Brown, Jr., Ohio  
L. H. Fountain, North Carolina  
Charles B. Rangel, New York

## Officers of the Executive Branch, Federal Government

Samuel R. Pierce, Jr., Secretary, Department of Housing and Urban Development  
James G. Watt, ACIR Chairman, Secretary, Department of the Interior  
Richard S. Williamson, Assistant to the President for Intergovernmental Affairs

## Governors

Lamar Alexander, ACIR Vice Chairman, Tennessee  
Bruce Babbitt, Arizona  
Forrest H. James, Jr., Alabama  
Richard A. Snelling, Vermont

## Mayors

Margaret T. Hance, Phoenix, Arizona  
Richard G. Hatcher, Gary, Indiana  
James Inhofe, Tulsa, Oklahoma  
Joseph P. Riley, Jr., Charleston, South Carolina

## State Legislators

Fred E. Anderson, President, Colorado State Senate  
Ross O. Doyen, President, Kansas State Senate  
Richard Hodes, Majority Leader, Florida House of Representatives

## Elected County Officials

Lynn G. Cutler, Board of Supervisors, Black Hawk County, Iowa  
Roy Orr, County Commissioner, Dallas County, Texas  
Peter F. Schabarum, Los Angeles County, California, Board of Supervisors

AN INFORMATION REPORT

# Tax Capacity of the Fifty States: Methodology and Estimates \$

ADVISORY COMMISSION ON  
INTERGOVERNMENTAL RELATIONS

WASHINGTON, DC, 20575  
MARCH 1982

**M-134**

# PREFACE

**T**he Advisory Commission on Intergovernmental Relations (ACIR) has had a longstanding interest in measuring the fiscal capacity of governments and in developing the Representative Tax System (RTS). The Commission has issued two prior information reports which have presented the rationale for, and procedures necessary to develop estimates of state tax capacity.

This third report allows policymakers, analysts, and the public to make interstate comparisons of fiscal capacity and tax effort for 1979.

The ability of a government to finance public services has typically been measured by the per capita income of its residents. However, income actually measures the economic well-being of a state's residents, which may differ substantially from the actual resources available for a government to tax. An alternative approach to measuring capacity—the Representative Tax System—combines 24 tax bases commonly used by the states to compile a composite index of state tax capacity. The system provides a comprehensive measure of each state's overall tax base that can be used in federal grant programs or for research purposes.

The RTS measures of tax capacity and tax effort might be considered for use in federal grant-in-aid formulas that are intended to provide some fiscal equalization. In addition, the estimates can be used by state officials who are interested in making comparisons between their states and others. In the past, the RTS has had a wide appeal among those keeping a watchful eye on state-local tax trends.

Conforming to ACIR policy on information reports, the results of the research are presented without recommendations. This report, however, provides statistical information that might be used by the President, Congress, and state legislative bodies in their consideration of policy issues.

Publication of this information report was approved by the Commission at its October 1981, meeting.

**James G. Watt**  
**Chairman**

# ACKNOWLEDGMENTS

**T**his report on the Representative Tax System was designed and prepared by Robert Lucke. Other members of the Taxation and Finance staff, including Albert Davis, Harvey Galper, Peggy Cuciti, and Susannah E. Calkins, reviewed the manuscript and made a number of helpful suggestions. Ruth Phillips and Shari Quick provided the secretarial assistance.

The following people also reviewed the draft report and offered valuable advice: Kent Halstead, Robert Reischauer, Dennis Zimmerman, Donald Curran, and Allen Manvel. In addition, special thanks are due to those individuals who attended a "critics' session" and provided many useful comments. The report would not have been possible without their cooperation and assistance and the Commission gratefully acknowledges their contribution.

Full responsibility for content and accuracy rests, of course, with the Commission and its staff.

**Wayne F. Anderson**  
Executive Director

**John Shannon**  
Assistant Director  
Taxation and Finance

# Introduction

**A**s early as the days of the drafting of the Articles of Confederation, there has been interest in measuring the relative capacity of states to raise tax revenue. In the drafting of the articles and subsequently the Constitution, the issue of how best to measure the “tax wealth” of the states arose in the debate over the apportionment of the expenses of the national government among the states. The northern states, finding themselves relatively wealthy, advocated a population basis for allocating expenses; the more populous southern states preferred that assessments be made according to the value of improved lands. Alexander Hamilton argued against both provisions on the basis that the relative ability of states to generate tax revenue could not be accurately measured by either population or land values; thus, policy based on such simplistic notions of tax wealth was inequitable:

The wealth of nations depends upon an infinite variety of causes. Situation, soil, climate, the nature of productions, the nature of the government, the genius of the citizens, the degree of information they possess, the state of commerce, of arts, of industry—these circumstances and many more, too complex, minute, or adventitious to admit of a particular specification, occasion differences hardly conceivable in the relative opulence and riches of different countries. The consequence clearly is that there can be no common measure of national wealth, and, of course, no general or stationary rule by which the ability of a state to pay taxes can be determined.<sup>1</sup>

Clearly, Hamilton had a prescient appreciation for the complexity involved in measuring the capacity of a state or local government to raise revenue. In spite of the difficulties suggested by Hamilton, economists, analysts, and policymakers have expended a great deal of time and effort in attempting to develop more reliable estimates of the capacity of the subfederal governments to finance public services. This ongoing interest in improving the measures of fiscal capacity is the result of the continuing desire to enhance the effectiveness of public policy specifically designed to ameliorate inter-jurisdictional fiscal disparities.

A number of major intergovernmental aid programs—General Revenue Sharing (GRS), Medicaid, Aid to Families with Dependent Children (AFDC)—allocate grant payments in an inverse relation to some measure of the recipient government's own ability to raise revenue. The motive for accurately measuring the recipient's fiscal capacity is to ensure that those units with lesser ability to raise revenue receive a relatively larger grant payment than their wealthier counterparts. In this connection, the Advisory Commission on Intergovernmental Relations went on record in 1964 as favoring the recognition of relative inequalities among the states in the distribution of federal grants to the states; that is, the Commission endorsed "fiscal equalization" as a desirable objective of federal grant policy.<sup>2</sup>

Broadly defined, fiscal capacity refers to the capability of a governmental entity to finance its public services. For present purposes, a jurisdiction's fiscal capacity will be discussed in a relative sense—i.e., its position vis-à-vis the national average—as distinguished from its maximum revenue potential.

It is especially important to recognize that fiscal capacity refers to the financing ability of *governments* rather than the economic well-being of *people*. Although a jurisdiction's fiscal capacity is highly dependent upon the prosperity of its residents, the relationship is by no means perfect. This is because governments can extract resources from nonresidents as well as from their own residents.

While there is general agreement concerning the concept of fiscal capacity and the need for accurate measurement, there is little consensus about the *method* of measurement. The federal government has typically used per capita income as a proxy for fiscal capacity and it is incorporated in many federal aid programs. State governments usually rely on per capita property values to reflect the fiscal capacity of substate jurisdictions.

The federal government's reliance on per capita income as the sole yardstick of fiscal capacity has been criticized in the past since the measure may not reflect

accurately a state's ability to raise revenue. In spite of this, the use of per capita income has been defended on the grounds that, although it is not the ideal measure, it is readily available and is easily understood. However, in light of the major changes that are occurring in intergovernmental fiscal relations, the use of the personal income measure needs to be critically reexamined.

This information report outlines a major alternative to the use of per capita income as a measure of fiscal capacity—the Representative Tax System (RTS) approach. This approach combines most state and local tax bases into a composite index of "tax capacity" or "tax wealth." The tax capacity of a state and its local governments is measured by the hypothetical amount of revenue that it would raise if it employed national average tax rates. Because rates are the same for each state, potential yields directly represent the strength of each state's overall tax base.

As part of the ACIR's ongoing interest in fiscal capacity indicators, this is the third statistical report issued by the Commission on the Representative Tax System.<sup>3</sup> In addition to incorporating much of the methodology of the earlier (1962 and 1971) ACIR reports, this edition includes many of the refinements and simplifications set forth in the studies of fiscal capacity by D. Kent Halstead and Robert Reischauer.<sup>4</sup> Because the ACIR reports were complex and could not be readily updated, Halstead and Reischauer modified the original RTS so that estimates can be calculated on an annual or biennial basis using, primarily, published statistics. This edition includes some additional improvements to the RTS methodology and presents the estimates in much the same format as Halstead's 1975 and 1977 reports. In order to permit consistent comparisons over time, revisions of Halstead's estimates based on the 1979 methodology are provided.

## WHY MEASURE FISCAL CAPACITY?

Studies of fiscal capacity provide quantitative information which is necessary in designing and administering the grants-in-aid used by the federal government to carry out its redistributive function. The estimates of fiscal capacity are used in allocation formulas which recognize the differences among the recipient jurisdictions in their ability to finance public services. Fiscal capacity is one of several factors by which grants are distributed; it has been used in combination with factors such as urban population, tax effort, or program expenditures (e.g., AFDC or Medicaid). Fiscal capacity

has always been measured by personal income in the federal grant programs in which it has been taken into account.

Federal grants to state and local governments have grown rapidly in the recent past, totaling approximately \$95 billion in FY 1980. Perhaps the most prominent federal grant to incorporate the equalization objective is General Revenue Sharing, which currently allocates \$4.6 billion to local governments. Two other major grant programs that utilize a fiscal capacity factor are AFDC (\$7.7 billion) and Medicaid (\$16.5 billion). According to a 1979 grant count, 29 federal programs used the per capita income measure (see *Appendix A*); their combined obligations were \$30.2 billion in FY 1979 and an estimated \$34.2 billion in FY 1980.<sup>5</sup> Although relatively few programs are explicitly designed to equalize fiscal capacity, such grants make up a relatively large slice of the total dollars spent for aid. Future consolidation of narrow-purpose categorical grants could increase this share if the resulting block grants are distributed according to capacity-conditioned formulas instead of on the basis of the historic allocations of the eliminated categorical aids.

Federal grants are not the only device for carrying out the equalization objective. State grants to local governments, particularly in response to calls for wealth-neutrality in public education, are geared to this goal—a goal of continuing importance because of court decisions emphasizing equal educational opportunities. Some states, such as Minnesota, Wisconsin, and Michigan, also have fairly large state-municipal revenue sharing programs that are designed to allocate grants in an equalizing fashion.<sup>6</sup> In addition, General Revenue Sharing allocates state-area shares to local jurisdictions according to a formula which includes a factor (per capita income) intended to mitigate intrastate disparities.

Fiscal capacity estimates also serve purposes beyond the allocation of federal or state grants. Such measures are of interest to state officials whose tax and spending policies frequently are shaped in the context of “not getting too far out of line” with neighboring states. State legislators are concerned with how their state’s tax policy will influence the investment decisions of potential and existing firms in their state.<sup>7</sup> Comparisons with nearby states and/or states with similar economic structures are certainly useful and instructive gauges in establishing tax policy. Without good measures of fiscal capacity, state policymakers cannot make meaningful comparisons of tax burden or “tax effort.” For example, in 1977, both Iowa and Louisiana had tax collections (state and local) that constituted 12% of their respective resident personal incomes. However, because Louisiana receives about 20% of its tax revenue from severance taxes, it might be a mistake to consider Louisiana’s resident tax burden on a par with Iowa’s. The improvement of the fiscal capacity measure would provide a sounder basis for policy decisions and, at the same time, provide information to the interested public for formulating and evaluating policy proposals.

The estimates of fiscal capacity provide insight into the changing fiscal demography of the country over time. That fiscal capacity differentials among the states or local areas are increasing or decreasing may have significant implications for both federal and state policy. Convergence may lessen the need for targeted assistance or reduce the concern about public service disparities. On the other hand, increasing fiscal disparities may reinforce the arguments for a stronger federal equalization role in the federal system or an expanded state government role in local finance. Indeed, it may be just as important for policymakers to know how each jurisdiction’s capacity is changing as it is to know its status at any given time.

# Approaches To Measuring Fiscal Capacity

## THE INCOME APPROACH

**P**ersonal income is often used by the federal government as a measure of fiscal capacity for grant programs that are intended to provide some equalization. The conceptual basis for the income approach is that, for the nation as a whole, aggregate national income represents the total resources available to meet both public and private-sector demands for goods and services. This holds for the public sector simply because—regardless of whether the tax is levied on income, sales, property, or some other base—it is generally paid from current income. Thus, it makes intuitive sense to measure each jurisdiction's fiscal capacity by its residents' income.

The ideal measure of a state's income would be based on a comprehensive income definition, such as a state level measurement of "net national product." It would include all wages and salaries, interest, dividends, and other earnings. In addition, it would include amounts for all capital gains, realized or unrealized; business profits; and imputed income of goods and services, such as housing, in-kind transfers, or household services. ("Imputed income" refers to the market value of goods and services which are earned by recipients in lieu of cash compensation. Examples are employee fringe benefits, the implicit net rental value of owner-occupied housing, and the market value of household functions performed by family members.) These amounts should be "grossed-up" to include collections from indirect business taxes (e.g., sales, property, and excise taxes). For the measurement of state-local fiscal capacity, income would be

computed *after* federal taxes and transfers, but *prior* to state and local taxes and transfers. Thus, it would include federal transfer payments and grants and deduct federal taxes, but it would exclude state and local transfer payments and not deduct state and local tax payments.

Income flows, other than those received by residents, should be included in the measurement of total state income. States can tax all income earned in a state, even though it may be received by persons in other states. Thus, state personal income should include corporate profits earned in one state and paid to shareholders in other states, as well as wages and salaries earned in a state by the residents of other states. In addition, a deduction for income taxes paid by the residents of one state to the governments of other states should be made from that state's income. Depending on the relative magnitudes of these residency adjustments, state income will differ from a resident income measure but will provide a more accurate measure of a state's fiscal resources.

Traditionally, the use of income as a measure of fiscal capacity has two basic advantages that make it attractive to both federal and state policymakers: (1) the estimates are available on a relatively current basis for both states and counties, and (2) the concept is easy to understand. These are significant factors in the political arena; and until now, these advantages seem to have outweighed any drawbacks in the use of per capita income as a measure of fiscal capacity.

## Measurement Problems

The reliance on income as a measure of fiscal capacity has been accepted with little discussion of its measurement and definitional difficulties. Presently, none of the income measures estimated by government agencies is based on a comprehensive definition of income. The income estimates of the U.S. Commerce Department's Bureau of Economic Analysis (BEA), its Bureau of the Census, and the Internal Revenue Service (IRS) exclude certain income components and can only serve as proxies for total state income. The primary difficulty in measuring state income is a lack of accurate and timely data for such items as imputed income, unrealized property income, and workplace/residency adjustments.

The alternative income measures that are currently available range from the relatively broad concept of income utilized by the BEA to the narrow definition of taxable income used by the IRS. Several income bases which are used by the federal government for grant allocations and other purposes are described below.

- *Resident Personal Income*: The BEA produces this

measure. It is a measure of all pretax income from wages, salaries, interest, rent, dividends, and transfer payments received by a state's residents. It also includes some nonmonetary sources of income, such as wages received in kind, inkind transfer payments (e.g., food stamps), and the imputed value of housing services for homeowners. Deducted from this measure of income are employee contributions for social insurance. This measure is available quarterly with a three-month lag, although it is subject to subsequent revisions. It is used in the formulas which allocate AFDC and Medicaid grants to the states. The BEA also estimates "disposable personal income" which is resident income less federal, state, and local income, estates and personal property taxes.

- *Money Income*: The Census Bureau uses this definition of income. It excludes all inkind income, is limited to monetary payments, and is calculated prior to the deduction of any taxes or social security contributions. Like the resident income measure, it is based on the residence of the income recipients. Data for this index are collected from the Decennial Census of Population and are updated periodically, using BEA and IRS income estimates. This is one of the income measures used in General Revenue Sharing allocations.
- *Adjusted Gross and Taxable Income*: Adjusted gross income is the IRS's broadest measure of income and is the starting point for calculating taxable income and personal income tax liabilities. It is based on all money income, subject to certain exclusions—such as business or moving expenses, alimony payments, capital losses, and 60% of capital gains. It also excludes nontaxable transfer payments, inkind income, and interest on state and local bonds, but includes personal social security contributions. In determining taxable income from adjusted gross income, other deductions are allowed for personal exemptions, the standard deduction—now referred to as the zero-bracket amount—and itemized deductions in excess of the zero-bracket amount.
- *Income by Place of Work*: This is an income-produced concept which is used by the BEA in the development of its resident personal income estimates. Essentially it consists of all wage and proprietary earnings paid within a jurisdiction, without regard to where recipients reside. Although it excludes property income—such as profits, interest, and rent—it may serve as a more

reasonable proxy for the relative economic strength of an area than does resident income.

The corresponding fiscal capacity indices for these different income concepts are shown in *Table 1*. The indices are constructed by dividing a state's per capita income for each measure by the respective national average.

The choice of which income measure to use is difficult. Because none of the measures is based on a comprehensive income concept, those measures are, at best, proxies for each state's total income. Each of the measures is based on a different definition and significant variations arise between the indices. Most importantly, the conceptual differences between the income received (resident personal income) and income produced (income by place of work) result in widely divergent results. Although not currently used in grant formulas, the measure of income produced is as justifiable a proxy for fiscal capacity as is resident income. This is because the volume of income generated within a state, regardless of where the recipients of that income reside, in large part determines the state's ability to raise revenue.

In fact, both income received and income produced provide a basis for taxation. Income *received* is taxed in the form of wages, salaries, interest, and dividends via the income tax; income *produced* is subject to taxation by general sales or gross receipts taxes, severance taxes, and commercial/industrial property taxes. While these two values are equivalent for the country as a whole, they are *not* for most states. Because the income that is produced in one jurisdiction may be received by the residents of other states, the differences that result from using income received or produced are largest in those states where metropolitan areas straddle state lines. This is especially important to Washington, DC, where the income received (BEA) index is 127, and the income produced measure is more than twice as large (281). Because the District is prohibited by Congress from imposing a payroll tax, the income-produced index is not an appropriate measure of its fiscal capacity. However, this is not the case for the 50 states which can subject all income earned within their borders to taxation, regardless of where the recipients reside.

Another measurement problem with the BEA income estimates (and to a lesser extent the IRS and Census estimates) is that they double count some types of income. The estimates include transfer payment income; they do not, however, deduct taxes paid by the residents of a state to finance those transfers, except for the employee share of social insurance contributions. The result of this double counting is the systematic *overstatement*

of the real income of those states in which government transfer programs, as well as taxes, are relatively large. In order to avoid this bias, income should be measured either by gross private income (i.e., *prior* to taxes paid and transfers) or post-fisc (i.e., *after* taxes and transfers). Although these two alternatives have differing conceptual bases, and yield different results, they are internally consistent in their treatment of the public sector. For state fiscal capacity purposes, the federal sector should be treated differently from state and local governments: income should be computed *before* state and local transactions but *after* federal taxes and transfers.

The alternative income measures also differ because of data limitations. Specifically, the BEA resident income indices are subject to measurement errors because they rely upon estimates of certain income components, such as proprietary income, military pay, imputed rental income, nonresident income, and farm income. These components are calculated from data that are not current and/or not available on a state-by-state basis. The result is a loss in precision.

The BEA, Census, and IRS income series present a range of income-received estimates that might be used to estimate fiscal capacity based on a resident income approach. While the differences between these measures are generally small, in some cases they are significant. For example, Maryland has a personal income index of 108 and a money-income index of 114—a difference of 5.6%.

## Conceptual Problems

Even if income could be precisely measured on a comprehensive basis, it would suffer from a very basic drawback as a measure of the ability of governments to raise revenue: it fails to come to grips with the diversity of state and local tax and revenue sources. State personal income would be a more useful indicator of fiscal capacity if the individual income tax played a larger role in state-local revenue systems. (In 1979, individual income taxes only accounted for 18% of state-local tax collections.) To be sure, most taxes are generally paid out of the taxpayer's income stream, but not necessarily at the point at which income is received. To the extent that governments rely on taxes which tap the income stream before or after it is received, resident personal income may not reflect a jurisdiction's fiscal capacity. Taxes are levied on income as it is produced (such as on corporate income and business property) and on income as it is used for consumption (such as on retail sales). As a result, income that households spend on consumption in states other than those in which they

live, or on products produced in other states, can be taxed by those nonresident states. Because states engage in efforts to shift tax burdens to nonresidents (within the constraints imposed by possible retaliation or law), these nonresident considerations are significant.

The major element of fiscal capacity for which the income approach fails to account is the ability of states

to impose taxes paid by nonresidents—a practice known as “*tax exporting*.” Because some states—such as the energy-rich or tourist-oriented—can enact taxes which are ultimately paid by nonresidents, they enjoy taxable capacity which is ultimately derived from an income stream extending beyond their borders. None of the measures of income successfully reflects the variety of

nonresident tax sources that can be tapped by state-local governments.

A variety of tax levies can be and are exported. If some part of the corporate income tax is shifted forward to consumers of the ultimate product and that product is purchased by out-of-state residents, the tax is exported. Every state has some share of its taxes exported, although

only a few states are large net exporters of home state tax levies. ("Net" exported taxes equal the amount a state exports less the amount it "imports.") For example, tourists are an important revenue source in a few states via the sales tax and special taxes on recreational activities—gambling, hotels, plays, etc. States exporting a significant share of their mineral production may be

able to shift a large portion of their severance taxes to the consuming states or to states where the producing corporations' shareholders reside. Although retaliation by other jurisdictions may limit the exportability of taxes, there is little question that it commonly occurs.

Tax exporting must be taken into account if an income approach is to be retained. However, it is extremely difficult—both as a measurement and as a conceptual issue—to adjust personal income so that it reflects the amount of taxes that each state can export or is forced to import. Because the ability to export taxes depends on varying economic circumstances, economists are not able to reach a consensus on the precise levels of exportation. In light of the difficulties with resident personal income caused by tax exporting, an alternative fiscal capacity measure—one that eliminates the need to measure exported taxes—would be a great improvement.

## The Need for Improvement

Historically, the need for improving upon income as a measure of fiscal capacity has been highlighted in studies of the revenue sharing program. In *Monitoring Revenue Sharing*, the authors concluded that the "revenue sharing law would be improved materially if it did not rely upon per capita income as a proxy of relative fiscal capacity. . . ." and recommended that state-by-state allocators be based on "annually updated estimates of total taxing or revenue-raising potential of the respective state areas."<sup>8</sup> Stephen Barro has suggested that, because states differ in their ability to export taxes, "a reasonable approach is to use a fiscal capacity measure based on the magnitudes of each separate tax base in a state—property, sales, income, etc.—combined into a single index with appropriate weights."<sup>9</sup> Thus, he concluded, "replacement of income by a general fiscal capacity measure provides a partial correction for the unequal abilities of different states to draw revenue from the incomes of nonresidents."<sup>10</sup> As long as there remain significant elements in state-local revenue systems which are unrelated to resident personal income, a composite measure of fiscal capacity will be superior to one based solely on the ability of the residents to pay taxes out of current earnings.

Recent developments have reinforced the necessity for replacing the resident income index. Rapidly rising energy prices and profits over the last two years have dramatically increased the fiscal capacity of a few states—a capacity which is not fully reflected in their per capita income. This distortion may be magnified in the future if the decontrol of oil and natural gas, in conjunction

with rising world energy prices, leads to increasing yields from energy-related tax bases. Like other distortions—such as the exportation of taxes on tourism—this misrepresentation of fiscal capacity is likely to be substantial and long term. An extreme example is Alaska, where it has been estimated that, in FY 1981, 95% of state government tax revenue will be provided by its energy resources.<sup>11</sup> If, however, the current slack in energy markets remains characteristic of the forthcoming years, the "energy distortion" will become less important.

The renewed push for grant consolidation, if successful, may result in the allocation of a greater part of the intergovernmental aid budget on a formula basis. For example, a block grant strategy that transforms many categorical grants into state/local entitlements that are allocated along the lines of General Revenue Sharing would significantly increase the importance of precisely measuring fiscal capacity. Indeed, the choice of which fiscal capacity indicator to utilize could be a major issue in the debate over grant consolidation and the "new" federalism. At present, the Reagan Administration is planning to allocate its new block grants according to a proportion of current entitlements. Eventually, a long-term system of block grants may have to be based on a new formula allocation system that reflects changes in fiscal capacity over time.

Consolidation and funding reductions in such grant areas as community development (CDBG) and urban development (UDAG), education, and health and social services will increase the importance of allocating payments where they are most needed. One suggestion for managing fewer federal dollars more effectively is to improve the targeting of these funds to the areas most in need. By assuring that those jurisdictions with the least ability to finance services on their own receive the most federal assistance, the impact of the administration's budget cuts on the most vulnerable will be tempered. This policy option has been suggested by Alice Rivlin, Director of the Congressional Budget Office, who emphasizes the need for a broader measure than personal income to measure fiscal ability.<sup>12</sup>

## Alternatives to Personal Income

States use a variety of tax and revenue instruments whose base may be only moderately related to resident personal income. For example, the correlation between resident income and retail sales is only .49. While in many cases the distribution of personal income may approximate the distribution of a nonincome-related tax

base, a measure of economic activity which is closer to the statutory basis of the tax itself generally will be more accurate. Although income may be a fair surrogate for a state's sales tax base, the total of retail sales is likely to be a much superior indicator. Similarly, corporate income would be a better measure than personal income of the strength of a state's corporate tax base.

In developing alternative measures to per capita income, analysts have looked into composite indices based on a number of revenue sources, such as income, sales, and property. The basic issues involved in designing such indices are (1) which revenue sources to include, and (2) how to combine the individual bases.

## **THE REPRESENTATIVE TAX SYSTEM APPROACH**

The ACIR staff has studied various measures of fiscal capacity and has suggested the Representative Tax System as an alternative approach to personal income. The Commission issued its first information report on this topic in 1962, presenting the rationale for, and procedures necessary to develop the Representative Tax System using this approach to estimate "tax capacity" or "tax wealth" for each state (using its combined state and local governments).

The Representative Tax System calculates tax capacity by estimating the amount of revenue that each state (and its local governments) would raise if an identical set of tax rates were used. The rates used in the calculation are "representative" in the sense that they are the national averages for each base. In addition, the state-by-state tax bases are standardized so that individual state tax practices—such as exemptions or partial assessment—do not affect a state's measured capacity. For example, the estimated full market value of residential housing is used as the base for the residential property tax. Because the same set of tax rates is used for every state, estimated tax yields vary only because of differences in the underlying tax bases. Thus, the hypothetical tax yields directly reflect the differences between states in overall tax base.

Although analytically complex, the Representative Tax System is a straightforward way of adding together each state's tax bases on a commensurate basis. By combining a wide variety of taxable resources—such as income, property, retail sales, and motor fuel—the Representative Tax System generates a broad index of a state's tax capacity. As a measure of fiscal capacity, this system has the major advantage that, for each source of tax revenue actually used, it measures the economic ac-

tivity subject to the tax. Unlike resident per capita income, the RTS method has the decided conceptual appeal that it does not rely solely on one measure of economic activity; it provides a measure of the multiple resources claimable by state and local governments through a variety of taxes.

All bases that are commonly subject to state and local taxation are used in the RTS calculation of tax capacity. The representative tax rates are applied in every state regardless of whether a given state actually taxes a particular base. Otherwise, tax capacity would be understated in those states that choose not to employ a full spectrum of taxes. For example, Connecticut does not have an income tax, but income is included in Connecticut's tax capacity estimate; similarly Oregon does not have a retail sales tax, but retail sales are included in its tax capacity computation.

The use of a representative set of tax rates for capacity measurement in no way implies that a state should use the representative rates in practice, nor do the tax capacity estimates depend on the actual set of tax rates employed by a state. The states exhibit a wide diversity in the tax instruments they use and the rates they apply. The RTS measures tax capacity independently of the tax mix or level a state employs, even if a given tax base is not taxed at all. Because the rates chosen are independent of the rates used by a given state, the system gauges tax capacity without regard to whether a state has generally high or low levels of taxation. The common set of tax rates used by the RTS reflects the typical behavior of all states and is not meant to be ideal or prescriptive.

For example, both Texas and Colorado have the same amount of retail sales per capita (\$3,738). The national average sales tax rate, when applied to both states, would raise \$235 per capita in tax revenue; thus each state's retail sales tax capacity would be the same—i.e., \$235 per capita. In reality, Texas (\$194 per capita) and Colorado (\$288 per capita) collect different amounts of tax from retail sales due to their differing tax rates. This tax rate variance, however, does not affect either state's retail sales tax base or its associated sales tax capacity. Because this principle applies to all bases in general, states will not differ in their capacities simply because of their choices in regard to tax rates or bases.

## **EXTENSIONS OF THE REPRESENTATIVE TAX SYSTEM**

The second ACIR report (1971) amplified the initial ACIR study of the RTS in two ways—by extending the

procedures and estimates to selected individual local areas and by including nontax revenue sources (i.e., user charges, fees, utility revenues, etc.). This system, referred to as the "average financing system," built upon the Representative Tax System methodology to account for state/local revenues other than taxes. In addition, this study extended the system to include 747 counties and 218 metropolitan areas and was much more complex and extensive than the original study that computed capacities only on a statewide basis.

Although the RTS has not yet been used in the U.S. grant system, Canada has incorporated the concept into its revenue equalization program. The fiscal capacity measure, provided by the Federal Provincial Fiscal Arrangements Act of 1967, is based on the Representative Tax System with some modifications. The purpose of the Canadian program is to equalize revenues among the provinces, and the capacity index used is built up from 29 revenue sources—including taxes and nontax sources of provincial revenue.<sup>13</sup>

## **Simplified Representative Tax System**

Building upon the ACIR reports, Robert Reischauer and Kent Halstead simplified the RTS methodology so that it can be updated annually or biennially, while maintaining the system's basic structure.<sup>14</sup> Incorporating their modifications, as well as some other refinements, the ACIR Taxation and Finance staff has recently reexamined the system and has developed the latest (1979) set of tax capacity estimates.

In order to produce the less complex measure of tax capacity, the core of the original ACIR methodology is retained, but the scope is narrowed. The tax capacity estimates are based only on taxes, thereby excluding nontax charges and fees, as well as a number of minor taxes. Also, the estimates are for states and their local governments combined; no estimates are developed for substate jurisdictions. By condensing the amount of time and effort required to develop state indices, timely and regular reports on state-area tax capacity can be produced.

The above simplifications ease the task of estimating tax capacity and allow the measures to be easily updated because most of the data are published regularly. As Halstead states,

The data. . . are limited to what is routinely published on a yearly basis. This has necessitated forsaking specific tabulations, surveys, and estimates of the sort that make the 1960

and 1967 indices such refined and valuable—but unreplicable—tools.<sup>15</sup>

While the advantages of simplification can be achieved at the expense of refinement and accuracy, it is of minor concern for the one year (1967) for which comparisons between the more complex ACIR measure and the simplified version can be made. Halstead found that for all but four states, the differences were 5% or less.<sup>16</sup> Although the comparisons for a single year do not eliminate all concern for the possible loss of accuracy of the simplified estimates, they are, nonetheless, reassuring.

The simplifications of the Representative Tax System estimates are a response to two competing policy requirements: (1) the need for a more accurate measure of fiscal capacity than per capita income, and (2) the desirability of a fairly simple, timely, and understandable measure. While maintaining the methodology of the original RTS, the simplified version reduces its complexity so that it can be consistently updated. Although less comprehensive than the average financing system, the simplified RTS accounts for most of the tax sources used by state and local governments and provides a broader measure of fiscal capacity than resident per capita income.

## **CRITIQUE OF THE REPRESENTATIVE TAX SYSTEM**

### **Measurement Problems**

As noted earlier, one of the continuing problems of the Representative Tax System methodology is that some of the necessary data on which it is based are not available on an annual or biennial basis. This necessitates the interim updating and projection of some of the required data series through the use of benchmarks and/or trend characteristics. For example, residential property values are only reported by the Census Bureau every five years—thus necessitating approximations during the intervening years. Another problem is caused by the need to rely on payroll data as a proxy for the state shares of the national commercial-industrial property tax base. Variations in methods used for estimating the underlying data have made the representative tax capacity indices susceptible to shifts over time due to the judgments of researchers, rather than to real changes in state and local fiscal capacity.

The property tax in particular remains a source of concern. The tax must be handled in several parts—residential, commercial, farm, public utility, and vacant land—each of which is separately estimated. According

to the authors of the 1962 ACIR report, "the application of the Representative Tax System poses nearly as many problems in the property tax area alone as in all the other taxes combined because the American property tax is a very complex, variegated institution."<sup>17</sup> This criticism remains valid for the simplified system as well.

Even though the Representative Tax System has been refined over time, as long as the methodology remains complex and subject to change, its validity for public policy will be challenged. In addition, policymakers place a premium on current data and are highly reluctant to make decisions based on data that do not become available for two or three years. These concerns are highlighted because of the existence of the personal income alternative—one that is already being estimated, is readily available, and is frequently used for capacity measurement purposes.

The major attractions of the Representative Tax System approach—its detail and specificity—are also the cause of its major limitations. Although the simplifications which have been made by Reischauer, Halstead, and the ACIR staff have produced a methodology that is less complex and easier to produce on an annual basis for state areas, data availability remains a source of inaccuracies.

In order to improve the consistency of the tax capacity measure, improvements in the underlying data are desirable. This potential for improvement, however, should not be used to prevent the adoption of the RTS approach. As Grasberger observes:

The RTS (Representative Tax System) measures, in spite of their shortcomings, are (as shown here) superior to fiscal capacity measures based solely on per capita personal income. The existence of shortcomings in available RTS measures should not be used as a justification for the outright rejection of the measure for formula analysis or formula modification purposes but rather stimulate intensive efforts to reduce or correct such shortcomings.<sup>18</sup>

The development of more consistent and timely data should accompany any decision by the federal government to incorporate this system into any intergovernmental aid program. The cost of collecting and analyzing biennial or annual data (solely for state areas) for use in the simplified Representative Tax System should not be prohibitive. Certainly the Census Bureau or Bureau of Economic Analysis could perform these duties much more efficiently and effectively than the individual researchers who have studied the Representative Tax System thus far. For local areas, however, the RTS suffers

from much more severe data limitations and the cost of data improvement is much greater.

## Conceptual Problems

Several conceptual criticisms of the Representative Tax System have been registered. According to John Akin, the "most serious fault" of the ACIR methodology is its failure to recognize the interrelated nature of the various tax bases.<sup>19</sup> Stated simply, no consideration is given to the possibility that the capacity to tax a given base will be affected by the size of another tax base. For example, the capacity of a state to tax residential property depends upon the income of the state's residents; thus a state with high income has a greater capacity to tax property than does a low income state. This conclusion is based on the assumption that the final incidence of the tax is borne by homeowners who pay their property taxes out of current earnings. Similarly, the capacity of a government to levy business property taxes depends upon the net income of a state's firms.

This point has intuitive appeal. Yet observing that tax bases are interrelated does not help quantify the strength of the relationship or the appropriate adjustment. While economic theory suggests that the value of residential housing is likely to be highly correlated with per capita income in the long run, and similarly, that the assets of businesses will represent their earning power, theory does not suggest how variances in these relationships affect fiscal capacity.

For example, suppose Ohio and Wyoming have the same per capita residential property values, but Wyoming's per capita income is 14% higher. Does this mean that Wyoming also has 14% more capacity to tax residential property? Or, is the true percentage somewhere between zero and 14? Attempts have been made statistically to estimate the relative contributions of current income and property wealth to fiscal capacity; however, these efforts have been limited by the difficulties in specifying the appropriate theoretical model and in statistically separating the influence of these factors. As a pragmatic response to this dilemma, the RTS assumes that the differing bases affect tax capacity in proportion to their revenue productivity. Thus, in the example above, while the RTS would give both Ohio and Wyoming equal residential property tax capacity it would also give Wyoming 14% more income tax capacity. If these were the only two tax bases available, Wyoming would have about 7% more overall capacity because each tax raises about the same amount of revenue.

A second drawback of the Representative Tax System

is its failure to account for the possibility that many of the revenue bases upon which such an index is grounded are not independent of government action. Reischauer raises the point that deliberate government policy, such as tax rates, zoning, and subsidies, affect the size of the tax base.<sup>20</sup> He cites numerous examples where state law inherently reduces or expands the size of a tax base. Such cases include the exclusionary zoning of commercial-industrial activity or of apartments; legalized horse and dog racing, which provide a base for parimutuel taxes; legalized gambling, which improves a state's amusement, liquor, and sales tax bases; liberal incorporation laws, which attract a larger corporation tax base.

To the extent that a state makes a conscious decision based on a trade-off between revenue and other social, environmental, psychological, and pecuniary costs, the RTS is not neutral with respect to state policy. For example, if California prohibits the construction of a nuclear power plant, and all other factors remain the same, it will reduce its tax capacity from what it would have been otherwise. Thus, to some extent states can manipulate the size of their tax bases and affect their tax capacity standing. The implication of this for federal grant allocation formulas based on tax capacity is that states will be penalized (through lower grant payments) for expanding their tax capacity and partially compensated for restricting it.

The size of a state's tax base is also affected by the state's choice of tax rates which raises problems for the Representative Tax System. For example, the RTS shows that New Hampshire has a high liquor tax capacity (i.e., relatively high per capita liquor sales) and a low liquor tax rate—suggesting that one of the primary reasons the state has a high liquor tax capacity is that it has a low rate. Another case is that of the property tax, where it has been shown that differences in tax rates relative to public services are capitalized into housing values: low tax states can have higher property values than they would have if they charged a higher rate, and vice versa.<sup>21</sup>

Theoretically, the Representative Tax System seeks to answer the question of how much revenue each state could generate if it taxed all of its bases at national average rates. Unfortunately, if all states taxed at the national average rate (for each tax base), the distribution of each tax base would certainly be different. This criticism is fairly serious, for it implies that the use of existing tax bases creates a systematic bias by understating the tax capacity for states with above average tax rates, and vice versa. Reischauer points out that a solution to this dilemma "is an impossibly difficult task, for researchers can only guess at the locational patterns of business, industry, sales, and population that would

result if all jurisdictions had the same institutional and legal (and fiscal) frameworks."<sup>22</sup> The significance of this criticism is mitigated, however, by the fact that personal income (as a measure of fiscal capacity) inherently suffers the *exact same* form of systematic bias for the identical reasons. In other words, personal income, as well as other tax bases, tends to gravitate away from high tax rate states.

## BEHAVIORAL MODELS

A different capacity measurement technique uses behavioral relationships to determine how the individual tax bases should be combined in order to compute a composite index for each jurisdiction. This behavioral approach attempts to address the criticisms of the RTS method—especially its insensitivity to possible feedback between tax rates and corresponding bases. Behavioral models are designed to recognize this interdependence and to make the appropriate adjustment for the interrelationship.

The behavioral approach seeks to estimate the determinants of state-local spending through econometric techniques.<sup>23</sup> Government spending is conceived as a function of variables such as the income and wealth of the residents, the percentage of taxes paid by the residents, resource prices, and a number of factors which relate to service needs and tastes. The expenditure equation is statistically estimated, and the coefficients of the capacity-related variables are used as the weights in the composite capacity index. For example, if \$1,000 of income "explains" \$100 of spending, and \$1,000 of property "explains" \$50 of spending, then income would be assigned a weight twice that of property.

This method relies solely upon income and property wealth as the fiscal capacity measures and finds that they are major determinants of state and local spending. This is intuitively appealing as the ability to bear tax burdens must necessarily be closely related to the economic well-being of the residents. However, because income and property wealth are the only measures used in the statistical models to account for all tax bases (such as sales and excises), the weights assigned to income and property are greater under this approach than they are under the RTS. The income and property variables serve as proxies for the omitted tax bases, but only in part. Income and property cannot account for the components of the other tax bases to which they are not systematically related. This is a significant drawback because tax sources, such as corporate income or mineral wealth, may have only a tenuous relationship to resident income or prop-

erty. The implication of this is that the behavioral approach cannot reflect real differences in fiscal capacity that arise from bases (or parts thereof) that are unrelated to the variables included in the model.

The behavioral approach also suffers from the theorists' limited ability to build complete models of expenditure determination that can disentangle all of the separate influences, and from the lack of knowledge about the true functional relationships among the variables. In addition, this approach is much more complex than the RTS in the manner in which the weights are determined. These considerations militate against its use for public policy, although further research in this area is clearly warranted and could prove useful in the future. Akin's recent theoretical work provides an important framework for the continuing evolution of this approach.<sup>24</sup>

## OTHER AD HOC APPROACHES

While both the ACIR's Representative Tax System

and the behavioral models offer sophisticated alternatives to the use of income as a measure of fiscal capacity, there are other composite indices. For example, fiscal capacity could be measured according to the amount of revenue a "model" revenue system would generate. In this manner, tax bases, such as income, property, or sales, would be weighted according to an "optimal" state-local revenue system. Because the resulting measures would inherently require normative judgments as to the ideal revenue structure, the estimates could be rightly challenged as being a reflection of nothing more than the particular values of a given analyst or group thereof. An index which is based on what "ought" to constitute fiscal capacity is arbitrary both in its selection of tax rates and in the bases to which they are assigned. In contrast, the Representative Tax System or the behavioral approach is attractive because each has a much firmer methodological basis. For example, the RTS uses weights that reflect each tax's share of the total revenue raised by the state-local government sector.

## The 1979 Tax Capacity Estimates

**T**he Representative Tax System includes all taxes which are in widespread use and for which there is an appropriate data series that reflects the distribution of the base. The tax bases included are (1) those taxed in states with more than half of the nation's population or (2) those bases where at least half the national base is taxed, regardless of the population of the states imposing the tax. In 1979, about 95% of state-local tax collections were raised from these bases. For each tax base that is included, a data series that has a common definition for all states is used to estimate the distribution of the base among the states. The state and local taxes used in the tax capacity calculation are shown in *Table 2*. The taxes which are not "representative," or for which there is not an appropriate state-by-state measure, have been excluded; these taxes amount to approximately \$10.8 billion or 5.3% of state-local tax collections. The largest of these are special state property, individual personal property, and documentary and stock transfer taxes. For purposes of the RTS some taxes (as reported by the Census Bureau) are reclassified. For example, West Virginia's gross receipts tax on businesses engaged in coal mining is treated as a severance tax, as is Alaska's special oil and gas corporate income tax. These adjustments are detailed in *Appendix B*.

*Table 2* also presents the tax base measures or proxies used to determine each state's comparative access to each tax base, and the national effective rate used for each tax source. The effective rates used in the Representative Tax System usually differ from those utilized in actual practice because the tax base measures do not exactly match the typical state's statutory tax base definition,

Table 2

## BASIC INFORMATION UNDERLYING THE REPRESENTATIVE TAX SYSTEM

	Amount (\$ millions)			Percent of

although the bases are often very similar. For example, the RTS uses total retail and service sales (less food and drugs) as a measure of the general sales tax base. Although this matches some states' sales tax base, states often use a broader definition of the base to include other businesses—such as wholesale trade, contracting, or manufacturing.

## STATE COMPARISONS

The 1979 state-by-state overall tax capacity estimates are shown in *Table 3*, along with the 1967 and the revised 1975 and 1977 measures.<sup>25</sup> The estimates are indexed based on the national tax capacity per capita for the respective year. For example, an index of 115 indicates that, on a per capita basis, the state has 15% more capacity than the national average for that year.

The 1979 capacity indices range from a low of 71 (Mississippi) to a high of 215 (Alaska). Twenty-eight states have capacities within ten percentage points of the national average; 41 states have indices within 20 points. The standard deviation of the capacity estimates is 24.4; when weighted by population, the standard deviation of the indices is 14.3. This indicates that, on average, an individual lives in a state with tax capacity that differs from the national norm by 14.3%. The states with the greatest capacities are Alaska (215), Wyoming (179), and Nevada (164), reflecting their ability to tax personal income that is beyond their borders. Alaska and Wyoming are wealthy mineral-exporting states and Nevada is heavily supported by its tourist trade.

In dollar terms, the average state in 1979 had a per capita tax capacity of \$884.29. Twenty-nine states had capacities that were within \$100 of the average. Alaska's fiscal capacity of \$1,903.17 per capita was three times that of the poorest state, Mississippi (\$628.49 per capita). Aside from the three exceptionally high states—Alaska, Wyoming, and Nevada—all states were within \$256 per capita (29%) of the national average.

The regional groupings indicate that the eastern states are relatively poor compared to their western brethren. The regions with the strongest overall tax bases are the Southwest and the Far West, which have capacities that exceed the national average by 16% and 15%, respectively. The Southeast region contains the poorest ranking states—Mississippi (71), Alabama (76), and Arkansas (78)—and that region's overall index (89) is the lowest in the nation.

## Comparisons Over Time

The fiscal capacity estimates for 1967, 1975, 1977,

and 1979 have been prepared on a largely comparable basis. Although some differences remain in methodology and data sources between the various years, significant changes between years should not arise because of these inconsistencies.

Some of the patterns revealed by the state time trends are:

1. The northeastern states (New England and Mideast) have been experiencing a long-term decline in tax capacity. New York, New Jersey, Connecticut, and Massachusetts have experienced a weakening in their fiscal bases. As a group, the Mideastern states have a capacity ten points below their 1967 value; the New England states have fallen by eight points. Recently, one of the most significant factors in the northeast's relative decline in tax capacity has been the slow growth which has occurred in the region's property tax base. Although home prices in the northeast have risen by 42.2% between 1975 and 1979, the national average home price has risen much faster (64.6%).<sup>26</sup> The northeast also has had relatively little new construction compared to the rest of the nation.
2. The tax capacity of the Midwestern states has remained fairly steady over this period—most states having had only small gains or losses, have maintained their relative standing. Although there do not appear to be any major secular trends in the region, their capacities have tended to fluctuate in step with national business cycles. This may be a result of their heavy dependence on income from farming and/or durable manufacturing.
3. Throughout the 12-year interval, the Southeastern states have remained fiscally weak. Although the states did experience a sharp rise between 1967 and 1975, their capacities have leveled off. In the late 1970s, the relatively poor states—such as Alabama, Arkansas, Mississippi, and South Carolina—did not experience any improvement whatsoever. These findings are consistent with trends in their personal income growth—rapid expansion in the 1960s and a slowing down in the middle 1970s. Louisiana and West Virginia have proven to be exceptions, showing continued fiscal growth because of their energy production.
4. The western states have exhibited strong growth in their relative tax capacities. Because of rising

property values and mineral wealth, many of the western states consistently increased their capacities throughout this period. Although California's capacity declined between 1967 and 1975, it has since started to increase. Between 1975 and 1979, the Southwestern, Rocky Mountain, and Far Western states have increased their capacities by six, four, and five percentage points, respectively. These relative gains have partially come at the expense of the eastern states—primarily those in the Mideast which have declined by seven points.

While the overall tax capacity trends in the 50 states suggest that there was movement toward fiscal capacity

equalization between 1967 and 1975, disparities have grown since then. One summary indicator of this is the standard deviation of the tax capacity estimates. The standard deviation declined between 1967 (18.5) and 1975 (17.77); grew slightly in 1977 (17.83); and rose to 24.4 in 1979. When weighted for population, the standard deviation shows the same trend: equalization from 14.6 in 1967 to 11.0 in 1975; some growth in disparities in 1977 to 11.8; further increasing to 14.3 in 1979. Thus, disparities in tax capacity are about the same now as those that existed in 1967. Although rising mineral wealth has clearly heightened the tax capacity of a number of the less populated states—such as Alaska and Wyoming—its impact on overall disparities has been somewhat muted because it is a relatively small part of the overall state-local revenue system.

---

## FOOTNOTES

<sup>25</sup> The ACIR staff has partially revised Halstead's 1977 and 1975 tax capacity estimates. These revisions include changes for the residential

property tax, the corporate income tax, the severance tax, and a residency adjustment for the income tax. The revisions were small for most states, but in some cases they were fairly substantial.

<sup>26</sup> National Association of Realtors, *Existing Home Sales*, Washington, DC, August 1980.

## Comparing Personal Income And The Representative Tax System

**I**n measuring state fiscal capacity, the choice between personal income and the Representative Tax System is a clear case of a “trade-off.” The per capita income measure is well established as a basis for measuring fiscal capacity. As a proxy measure, it has the dual advantages of being readily understandable and available on an annual basis. Thus far, these advantages—its simplicity, availability, and familiarity—have been decisive, certainly for policymakers.

Although the RTS is a better measure conceptually than is per capita income, if it yields similar results, the cost of its development may not be justified. The magnitude of the differences between per capita income and tax capacity is a key issue in the choice of which measure is better suited for public policy. If the differences are not great, and are declining, personal income should be utilized because it is easier to comprehend and it is already produced. The larger the variations, however, the more compelling the case for considering the RTS because of its superior conceptual framework for measuring a state’s fiscal resources.

Comparisons have been made between resident personal income (BEA) and tax capacity estimates for 1967, 1975, 1977, and 1979, using the simplified version of the RTS. In making comparisons it must be stressed that while the two series differ, the differences in and of themselves do not suggest which of the estimates is “better.” This decision must be made on conceptual grounds and on considerations such as data accuracy, reliability and availability, and the appropriateness of the methodology used.

*Table 3* presented the 1967, 1975, 1977, and 1979

state-by-state indices of resident per capita income (BEA), as well as the simplified Representative Tax System estimates. How well resident personal income conforms to the RTS measure of tax capacity is indicated by correlation analysis. Although the correlation coefficients between income and tax capacity show a moderate-to-strong relationship between the measures—.70 in 1979, .77 in 1977, .76 in 1975, and .70 in 1967—they indicate that significant differences exist between them. For a relatively large number of states the measures are fairly close; but in a few states—most notably the energy-rich or those that rely heavily on tourism—the differences are quite large. Were it not for these exceptions, there would be little reason to discontinue the use of per capita income as a proxy for fiscal capacity.

The comparisons between personal income and the RTS yield these findings:

1. The two series are fairly close together for most states. The differences between the two measures of fiscal capacity for many states are not significant. The 1979 estimates show that 27 states have tax capacity and per capita income indices that differ by five or fewer percentage points. Fourteen states and the District of Columbia, however, have indices that differ by more than ten points. These states are shown below.

<b>Percentage Point Differences: Per Capita Income Less Tax Capacity, 1979</b>	
Alaska	-87
Wyoming	-66
Nevada	-44
Montana	-23
Louisiana	-22
Texas	-22
New Mexico	-19
Oklahoma	-16
North Dakota	-12
West Virginia	-11
New Jersey	+10
Massachusetts	+10
District of Columbia	+13
Rhode Island	+13
New York	+17

SOURCE: See Table 3.

2. The differences in per capita income and tax capacity show a distinct regional pattern. Of the northeastern states, only New Hampshire, Vermont, and Delaware have tax capacity in excess

of their per capita income. Conversely, all western states, with the exceptions of Washington, Arizona, and Hawaii, have tax capacity in excess of their per capita income. This is a reflection of relatively high per capita property and mineral values in the west relative to the northeast.

3. The correspondence between the per capita income and tax capacity series improved between 1967 and 1975, and remained substantially unchanged in 1977. The 1979 estimates, however, show an increased divergence. This is partially attributable to the rapid escalation in energy prices during 1978-79 which in turn caused rapid increases in the tax capacity of the mineral-producing states.

In addition to expanding the severance tax base of these states, the rise in oil prices also increased their corporate property and corporate income tax bases. The percentage changes in tax capacity and per capita income between 1975 and 1977, and between 1977 and 1979, for the eight largest energy-producing states reflect the impact of the large increases in energy prices that occurred in 1978 and 1979:

	<b>Change in Per Capita Tax Capacity Index</b>	
	<b>1975-77</b>	<b>1977-79</b>
Alaska	-3.1%	+39.6%
Wyoming	-1.9	+12.6
New Mexico	+6.5	+4.0
Texas	-0-	+5.2
Louisiana	+1.0	+4.9
Oklahoma	+1.9	+7.6
West Virginia	+1.1	+5.6
Kansas	-3.7	+2.9
	<b>Change in Per Capita Income Index</b>	
	<b>1975-77</b>	<b>1977-79</b>
Alaska	-9.7%	-14.1%
Wyoming	+2.9	+4.6
New Mexico	-0-	+3.6
Texas	+3.2	+2.0
Louisiana	+3.7	+1.1
Oklahoma	+2.2	+6.6
West Virginia	-0-	-1.2
Kansas	-2.0	+5.0

SOURCE: See Table 3.

While the energy-producing states had tax capacity indices that remained fairly stable between 1975 and 1977, these states all experienced fairly large increases in their capacities between 1977 and 1979. In contrast, the per capita income indices show mixed results for both periods and fail to indicate that the increase in energy prices between 1977 and 1979 has had a significant impact on state fiscal capacities.

4. The tax capacity and income indices reveal differing trends in fiscal capacity equalization among the states. The per capita income indices have shown a consistent convergence (as measured by the standard deviation) between 1967 and 1979. The opposite is the case for the tax capacity measures; the tax capacity series converged between 1967 and 1975, and has since shown an increasing variation. Thus, not only do the tax capacity estimates now reflect a wider variance than per capita income, they also have been moving in opposite directions:

	Standard Deviation (population-weighted)	
	Tax Capacity	Per Capita Income
<b>1967</b>	14.6	15.4
<b>1975</b>	11.0	11.7
<b>1977</b>	11.8	10.7
<b>1979</b>	14.3	10.1

That the tax capacity variance is larger than that of per capita income indicates that tax sources other than income are more unevenly distributed among the states than is personal income. Indeed, one of the prime advantages of the tax capacity estimates is that they explicitly take into account sources which are *not* distributed among the states according to income.

5. For most states the income indices show smooth

trends over the period covered—a trend which is also a characteristic of the tax capacity estimates. Some secular trends—such as the shift of tax capacity from the northeast to the west—are evident. The cyclical trends that are present in the per capita income series are the result of changes in the business conditions that have occurred over the five-year period, such as the good year for the automobile industry in 1977 and the bad years in 1975 and 1979, or the bad year for farmers in 1977.

The tax capacity series also reflect these cyclical changes in personal income, as well as long-term shifts in relative property values and mineral production. For example, the tax capacity series takes into account the regional variability in property values—the average single family home in the west went up in price by more than twice as much as those in the northeast (102.7% vs. 45.2%).

These comparisons point up the limitations of the per capita income approach to fiscal capacity measurement. As a single measure of economic activity, per capita income cannot possibly reflect the nuances of state-local revenue systems and their reliance on a wide variety of tax sources. To be sure, income is a measure of the economic well-being of a state's residents. However, this is not synonymous with the overall objective: *the measurement of the capability of governments to raise revenue*. By implicitly incorporating the ability to tax nonresident income and previously accrued income (in the form of property wealth), the tax capacity approach is better able to achieve this goal. While the Representative Tax System may be less accurately estimated than is per capita income, "it is better to be imprecisely right than precisely wrong."

# Sensitivity Analysis Of The Representative Tax System Estimates

**T**he Representative Tax System estimates presented in this report account for the 24 different tax sources detailed in *Appendix B*. In 1979, these sources produced approximately \$195 billion, or about 95% of total state-local tax revenue. In order to improve the precision of the standard capacity estimates, it may be desirable also to account for other sources of revenue, such as the omitted taxes, user charges, or interest income. Alternatively, by excluding some minor taxes, it may be possible to develop a simpler measure of tax capacity. The sensitivity of the standard measure to these types of alterations is a consideration in the decision of how complex to make the RTS. The 1979 tax capacity estimates are shown in the first column of *Table 4*. The second through fifth columns present variations of the standard Representative Tax System based on different levels of revenue coverage as outlined below. For reference, the 1979 resident per capita income estimates are provided in the sixth column.

Of the 24 tax bases included in the standard system, many produce only a limited amount of revenue. In order to further streamline the RTS, it is possible to omit these relatively minor taxes to reduce the complexity of the system and make it easier to update the estimates. The second column presents tax capacity estimates based on a "condensed" RTS using only ten tax sources: general sales, personal income, property (the five components), and severance (the three components) taxes. The standard and condensed capacity estimates are very closely related; only one state (Alaska) has an estimate that differs by more than 10%, and only seven states differ by more than 5%. The correlation between the two series

Notes:

Condensed RTS: Tax capacity calculated using only individual income, retail sales, property, and severance tax bases.

Expanded Variations:

#1: Standard tax capacity plus miscellaneous taxes.

#2: Standard tax capacity plus miscellaneous taxes, user charges, and interest income.

#3: Standard tax capacity plus miscellaneous taxes, user charges, interest income, and energy royalties.

SOURCE: ACIR staff estimates.

is nearly perfect (.991) and suggests that the additional 14 taxes add very little precision to the more general index. This condensed index is a very good approximation of the larger RTS and shows that the standard system is not very sensitive to the omission of the relatively minor taxes employed by state and local governments.

In contrast to this condensed tax capacity index, a more comprehensive indicator of tax capacity can be constructed to include the \$10.8 billion (5.3%) of state and local taxes that are omitted from the standard RTS formulation. The criticism has been made that anything less than 100% coverage of state-local taxes, however atypical, will bias the tax capacity estimates. Including these other taxes adds to the completeness of the RTS by accounting for all taxes used by the state-local sector. Because the miscellaneous taxes do not draw upon a standard tax base, as do the other taxes, proxies have to be used to measure the distribution of these bases among the states. The "other taxes" have been grouped into three categories for this purpose. For selected sales taxes (\$2.2 billion), other than those already incorporated in the RTS, the relevant base is assumed to be distributed in proportion to the general retail sales tax base. Examples of such taxes include special levies on motels, soft drinks, or firearms. Special taxes (\$.8 billion) that tap a relatively unique base—such as timber taxes or stock transfer taxes—are added directly to a state's estimated yield from the Representative Tax System; that is, the revenue from these types of taxes is used as a proxy for the base. Finally, the base for all other remaining taxes (\$7.9 billion)—such as personal property taxes on automobiles, or business and occupation taxes—is measured in proportion to each state's disposable personal income.

The resulting tax capacity estimates from the inclusion of the other taxes are shown in column 3. The effect of this adjustment to the standard RTS estimates is very small; no state has estimates that differ by more than 4%, and only Wyoming (-4) and New York (+3) have indices that differ by more than two percentage points. The correlation (.999) between the two series indicates that there is almost no effect on the standard tax capacity indices when the miscellaneous taxes are included in the calculation.

A further extension of the RTS approach is to include measures of the ability of governments to earn interest and to employ user charges. This "average financing system" is a simplified version of the system presented in the 1971 ACIR report that included these two nontax sources of revenue in determining state capacity. In 1979, user charges (exclusive of those generated from

utilities and state liquor stores) amounted to \$39.5 billion, and interest income earned by states and localities was \$11.8 billion.

Estimates of the average financing system were derived by using proxies to estimate the distribution of the base for both interest and user charges. The capacity of a state to impose user charges was measured in proportion to each state's disposable personal income. Although the underlying assumption that capacity to pay user charges is directly related to disposable income is imperfect because charges are imposed on both individuals and businesses, the present data do not allow such distinctions. Interest was handled in the same manner as special taxes (i.e., income from that source was added directly to the estimated yield of the RTS in a state). The average financing estimates also include the adjustments made for miscellaneous taxes as described above.

The average financing indices in column 4 reveal that there is little difference between the results for the average financing system and those for the standard Representative Tax System. Although the differences are larger than when only the miscellaneous taxes are included, they are relatively small. Only four states—Wyoming (-13), Oregon (+7), Nevada (-11) and New York (+7)—show indices that differ by more than six percentage points. The correlation between the two series (.991) reflects the strong relationship between the estimates and indicates that the inclusion of these other sources of revenue generally is not important.

The third expanded RTS measure presented in column 5 includes mineral royalties as a state revenue source. Royalty revenue is added directly to the yield of the system and increases the measured capacities of those states with mineral production on state and federally owned lands. This version is the most comprehensive and its results match the standard RTS very closely; the correlation is .981. Seven states differ by more than five percentage points, the largest difference being for Alaska whose index is 33 points higher. By providing the greatest coverage of tax and other revenue sources, this version probably produces a better gauge of overall revenue capacity than does the standard RTS.

The robustness of the standard tax capacity estimates is revealed by the correlation (.997) between the narrow measure of tax capacity based on only ten sources and the most comprehensive average financing estimates. Once the core of the state-local revenue system—income, general sales, property and minerals—is accounted for, the tax capacity estimates are very stable.

None of the alternative formulations of the Representative Tax System presented here materially affects the relatively poor relationship between personal income

and the more comprehensive capacity measures; the correlations between resident per capita income and the alternative tax capacity indices range from .688 to .752. Each of the different formulations of the RTS produces estimates of tax capacity that are consistently different (in both direction and magnitude) from resident per cap-

ita income. Although accounting for a wider range of government revenues undoubtedly yields a more accurate tax capacity measure, even the narrow-based RTS formulation produces consistent results that would be a substantial improvement over resident per capita income as a measure of fiscal capacity.

## Case Study:

# The Impact Of Tax Capacity On Medicaid

The estimates of tax capacity which result from the Representative Tax System can replace the present indicator of fiscal ability—per capita income—in various federal-state grant programs. The biggest program utilizing personal income as a primary allocation factor is Medicaid. Each state's grant allocation is basically determined by the product of the amount the state chooses to spend on Medicaid benefits and its federal matching share (FMS). The FMS<sub>i</sub> for state "i" is determined by the equation:

$$FMS_i = 1 - .45(PCI_i/PCI_{us})^2$$

where PCI<sub>i</sub> is the per capita income in state "i" and PCI<sub>us</sub> is the national average per capita income. The income factor used in the formula is a three-year average using BEA's estimate of resident per capita income. The federal matching share has a minimum of .5 and a ceiling of .83. The way the formula is constructed, a state with average income will have a matching share of .55; that is, the federal government pays 55% of the state's Medicaid benefits. Because state per capita income is the only variable in the formula that changes from state to state, the federal matching share will only vary between two states if they have differing per capita incomes—the higher income states having lower matching shares, and vice versa.

The 1981–82 Medicaid matching shares that would result from the simple replacement of per capita income with latest tax capacity estimates (1979) for each state are shown in *Table 5*.

The use of tax capacity instead of per capita income would have a small effect on the matching shares for

Revised Formula #4:  $FMS_i = 1 - .45 \left( \frac{TC_i}{TC_{us}} + \frac{POV_{us}}{POV_i} \right)^2$ ; Minimum FMS = .50; Maximum FMS = .83; POV, = percent of state i's population below the poverty line.

Notes: <sup>1</sup> Amounts are in millions of dollars. The "gain" or "loss"

refers to the difference in a state's allocation based on the existing formula which uses per capita income.

<sup>2</sup> Amounts are in dollars.

SOURCE: ACIR staff estimates.

most states. The FMS would change by less than five percentage points in 36 states and the District of Columbia. Because of the minimum (50%) matching rate provision in the formula, seven states and the District of Columbia would experience no change whatsoever. In contrast, New York (+15.13) and Rhode Island (+10.84) would have their federal shares increased substantially; while New Mexico (-17.19), Louisiana (-16.85), and Montana (-15.34) would experience large reductions.

Table 5 also presents the approximate dollar changes in federal FY 1982 aid for Medicaid that would occur if per capita income is replaced by tax capacity. These estimates assume that states will maintain their benefit levels and eligibility criteria; that is, their behavior will not be altered as a result of changes in their matching shares. The overall cost of such a change to the U.S. Treasury would be \$929.9 million.

New York clearly stands out as the largest beneficiary from such a change—a result of the state's high benefit levels combined with the correction of the large overstatement by income of its tax capacity. In per capita terms, New York would gain \$46.98 from such a change; in contrast, Louisiana would lose \$22.50 per capita. In general, the northeastern states would gain from the substitution of tax capacity for per capita income and the western states would lose. Because there is a strong tendency for personal income to neglect fiscal capacity that arises from mineral or property wealth, states that are relatively well-endowed with these tax sources will receive reduced shares as a result of the simple replacement of the income index with tax capacity in any federal aid formula.

This simulation demonstrates that, for a number of states, the fiscal capacity measure chosen by Congress for a grant allocation formula is of substantial financial importance. Similarly, this hypothetical exercise indicates the level of costs or benefits now conferred upon individual states by the failure to use a more comprehensive yardstick of fiscal capacity.

These results, while illustrative of fiscal capacity measurement, do not by themselves show which measure—per capita income or tax capacity—better reflects the distribution of fiscal capacity among the states. That judgment must be made independently of the results presented by a computer printout and must rest on conceptual and methodological grounds. However, any subsequent decision to use the tax-capacity factor in aid formulas will involve wider formula distribution issues and questions of political feasibility. It is up to Congress to decide (1) whether it wants to use a fiscal capacity measure in grant-in-aid formulas, and (2) if so, how it ought to be incorporated (e.g., multiplicatively, squared,

inverted, etc.).

Whether Congress will move to substitute tax capacity for per capita income in Medicaid (or other grant programs) will, in practice, depend on the resulting distribution of “winners” and “losers.” Clearly, if the simple substitution of tax capacity for per capita income in Medicaid yields a politically unacceptable distribution of grant payments, Congress will reject that approach. In order to design a formula that is politically acceptable, Congress might choose to use the tax capacity measure *in combination with* other formula changes.

There are a number of ways in which the Medicaid formula can be changed, in addition to replacing per capita income with tax capacity. Table 6 presents the changes (in total and on a per capita basis) that each state would experience in FY 1982 if tax capacity were used in the formula in combination with other adjustments. The overall results presented in the table demonstrate that distributions can be affected in a number of ways—each yielding a different distribution of Medicaid payments to the states.

The alternative Medicaid formulas, and why they were chosen, are described below. In all cases, per capita income has been replaced by tax capacity.

1. The federal matching share minimum has been reduced from 50% to 40%. The 83% ceiling has been lowered to 57%. The equation to determine the FMS is the same as that stipulated by current law, with the exception of the replacement of income with tax capacity (TC):  $FMS_i = 1 - .45(TC_i/TC_{us})^2$ . The 40% floor and the 57% ceiling have been recently proposed in Congress: the 40% floor in the Senate, the 57% ceiling in the House.
2. The federal matching minimum has been reduced to 40%; the ceiling is retained at 83%. The squaring factor has been eliminated. The new equation is:  $FMS_i = 1 - .45(TC_i/TC_{us})$ . The squaring term is removed in order to reduce the disproportionate variation of matching shares that results from using a squaring factor.
3. The federal matching minimum has been reduced to 40%; the ceiling is retained at 83%. Medicaid expenditures eligible for aid in each state have been capped at \$226.16 per capita (150% of the national per capita average). The squaring term is retained. The equation is:  $FMS_i = 1 - .45(TC_i/TC_{us})^2$ . The cap on expenditures is included to limit federal distributions to states with unusually high benefit levels and/or caseloads.

4. The federal matching minimum is retained at 50%; the ceiling is 83%. A “need” factor—the ratio of the national percentage of the population below the poverty line ( $POV_{us}$ ) to the percentage of state  $i$ 's population below the poverty line ( $POV_i$ )—has been given equal weight to the capacity factor in the formula. The squaring factor is retained. The formula is:  $FMS_i = 1 - .45(((TC_i/TC_{us}) + (POV_{us}/POV_i))/2)^2$ . The need factor is included to demonstrate that need can be treated in a fashion similar to capacity in the formula.

These are just a few of the alterations that could be made to the existing formula. What is striking about them is their vastly different results. For example, New York gains \$829 million under the current formula using tax capacity, but loses \$153 million under the third re-

vised formula; in contrast, Texas loses \$239 million under the first and third formulas, but gains \$12 million under the fourth. The federal share ceiling and floor, the squaring term, and the incorporation of the need factor can have substantial impacts on the payments to the states which can reinforce or reverse the impact of the replacement of per capita income with tax capacity.

The redistribution of federal aid among the states is often a politically divisive issue. The simple replacement of per capita income with tax capacity could increase regional tensions because it would tend to shift resources from the west to the northeast. Especially in times of budget retrenchment, the shift of resources between states and regions will be difficult for Congress. One way of reducing regional conflicts would be to phase-in use of the tax capacity measure; alternatively, Congress might choose to limit its use to new or consolidated grant programs which do not currently use a fiscal capacity factor.

# Measuring State Tax Effort

## THE REPRESENTATIVE TAX SYSTEM MEASURE OF TAX EFFORT

**B**y providing a more comprehensive measure of state taxing ability, the Representative Tax System also provides the basis for making a more accurate reading of state tax efforts. Typically, the "tax effort" of a state is measured by taking the ratio of a state's tax collections to its resident income or population. When fiscal capacity is estimated by the RTS, a state's tax effort can be measured by the ratio of its total tax collections to its total tax capacity. *Table 7* presents the overall tax effort indices for 1967, 1975, 1977, and 1979 based on the RTS. A tax effort of greater than 100 indicates that a state is taxing its overall base at greater than average rates, and vice versa. In addition to the overall tax effort index, an effort index can be calculated for each of the separate tax base categories.

The 1979 tax effort indices range from a high of 172 for New York to a low of 63 for Texas. This implies that, on average, New York's tax rates are 72% above the national average and 173% above those of the lowest state. In dollar amounts, Alaska (\$2,406.38 per capita) collects more tax revenue than New York (\$1,318.88 per capita); however, New York's tax effort is much higher because of its relatively weak tax capacity. Arkansas collects the fewest taxes per capita (\$568.70), which is about 64% of the national average per capita (\$884.29).

On a regional basis, the tax efforts exerted by the New

England and Mideastern states are the highest. With the exceptions of New Hampshire and Delaware, all states in the northeast, have tax efforts which are above the national average. In contrast, all Southeastern and Southwestern states except Arizona exhibit a tax effort below the national average. The high efforts in the northeast are a function of both high collections and low fiscal capacity; the low efforts in the south are primarily the result of low collections. Although the western states have collections that are above the national average, they exert relatively low efforts because of their generally high capacity levels.

The tax effort factor produced by the RTS can be used in intergovernmental aid formulas, such as General Revenue Sharing. In so far as tax capacity is a better measure than resident income, tax effort is more accurately measured in relation to tax capacity than to income. Because the use of tax effort in aid formulas generally provides an incentive for states to increase their own taxes, its use as a formula factor has been seriously questioned by proponents of a smaller governmental sector. The issue of whether or not federal aid formulas ought to include a tax effort factor at all, however, is an issue unrelated to its appropriate measurement.

Although the Representative Tax System index of tax effort is a useful device to compare state tax policies, it should not be used to measure resident tax burdens. The tax effort measure has a narrow interpretation; it is an overall estimate of how heavily a given state taxes all of its tax bases. The tax effort measure fails to gauge accurately resident tax burdens because some states are able to shift burdens to taxpayers in other states. The effort measure does not make a distinction between resident and nonresident tax collections. For example, Alaska shows a high measure of tax effort because it relies very heavily on its energy resources through the severance, corporate income, and property taxes. Because these taxes are partially shifted to nonresident taxpayers, it would be a mistake to assume that resident burdens in Alaska are reflected in its high tax effort index.

## FISCAL BLOOD PRESSURE

The fiscal "blood pressure" index presented in this report has not been included in earlier studies of fiscal capacity. Pioneered by the ACIR, fiscal blood pressure is a two-dimensional measure which provides a view of how state tax efforts have changed over time, as well as their level at a given point in time.<sup>28</sup> The index is a two component measure: the first number is a state's

current tax effort (1979) index; the second is the ratio of the current index to that of a prior year (1975 or 1967). For example, an index of 112/80 indicates that the state's effort is 12% above average, but that it has fallen by 20% since the base year.

The fiscal blood pressure index has been developed because it is thought that a static measure of tax effort does not present an adequate portrayal of state fiscal strain. The rate at which a state's tax effort is changing is a significant indicator of state fiscal stress because it reflects how taxpayer burdens are shifting. That a state's tax effort is high and *rising* can produce different pressures for state policy action than if it is high and *falling*. This distinction is certainly relevant for policymakers who keep close watch over state tax trends.

The blood pressure index combines two of the primary factors that "cause" fiscal strain—the change in tax collections and the change in fiscal capacity. A rising blood pressure can reflect an increase in tax collections and/or a decline in tax capacity. By relating changes in tax collections to changes in capacity, the index indicates whether taxes have increased faster or slower than the state's taxable resources. Because the index is a relative measure, it is especially useful during inflationary times when it is difficult to make comparisons between different years based on nominal amounts.

The fiscal blood pressure estimates for 1979 are shown in *Table 8*. The indices (1) reflect each state's 1979 tax effort and its relative change since 1975 and 1967, respectively, and (2) reveal large differences in fiscal blood pressure among the states.

The northeastern states generally exhibit above-average tax efforts which have been rising over time. Over both the 1975–79 and 1967–79 periods, the region was characterized by high *and* rising tax efforts: the New England states (122/112) and the Mideastern states (134/116) exhibited tax effort increases over the 1967–79 period of 12% and 16%, respectively. These changes were the result of a combination of increasing tax collections, as well as declining tax capacity; the New England and Mideastern states experienced reductions in tax capacity of 8% and 10%, respectively. Thus, the decline in tax capacity was the major contributor to the rising tax efforts, with increasing collections playing a minor role.

New York exerts the highest tax effort (172) of any state, and its effort has risen by 25% since 1967. In that time the state's relative capacity has declined by 19% and its collections have increased 6% faster than the national average. Between 1975 and 1979, New York's increase in tax effort (+8.0%) can be completely attributed to a reduction in tax capacity (–9.4%) because its collections have actually increased less than the na-

tional average rate. In recent years, it appears that New York's high fiscal blood pressure has been primarily a function of a declining tax base and *not* of a rapidly expanding public sector.

Both the Great Lakes and the Plains regions exhibit average tax efforts and have experienced only mild changes since 1967. Indiana, Ohio, North Dakota, and South Dakota all have tax efforts which are less than 90% of the national average, and only Ohio has experienced some upward movement. Although Illinois's tax effort rose by 18% between 1967 and 1979, the entire increase occurred before 1975. Minnesota and Wisconsin have the highest efforts in the Midwest, efforts which declined marginally during 1967-79.

The Southeastern states exhibit generally low tax efforts that have essentially remained unchanged since 1967. Although their tax efforts declined between 1967 and 1975, they subsequently rose in the later period (1975-79). Mississippi (96) and Georgia (97) are the only states in the region whose efforts are in excess of 95% of the national average. These generally low tax efforts, however, partially reflect the greater reliance

which the southern states place on user charges and fees as a source of government revenue.

The three western regions exhibit below average and declining tax efforts. Of the 15 western states, only Arizona (116), Alaska (126), and Hawaii (128) have tax efforts in excess of the national average. Nevada (65) and Texas (63) exert the lowest tax efforts in the nation and their efforts declined over the 1967-79 period. Although Alaska and Wyoming have shown increasing tax efforts, this is largely due to rising mineral revenues.

California's tax effort (95) is below the national average and reflects the impact of Proposition 13. After rising by 10% between 1967 and 1975, the state's tax effort declined by 20% between 1975 and 1979. In 1975, the state's tax effort was 19% above the national average; in 1979, it was 5% below the average.

## State Charts And Tax Tables

**T**his chapter presents two sets of tables that detail the tax capacity estimates by state and type of tax. The first set of tables presents an overview of each state's current fiscal status. Breakdowns of tax capacity and effort are provided for eight tax categories; information on a state's total dollar, per capita, and relative tax capacity and effort for each category is presented. In addition, the difference between a state's actual tax collections and its capacity for each tax is provided as an indicator of how heavily a state taxes each source.

The tax capacity and effort estimates for 1967, 1975, and 1977 are also provided. These estimates reflect the changes in a state's capacity and suggest how it might be changing relative to its neighbors and the rest of the nation. The tax effort and fiscal blood pressure indices compare each state's tax effort with its historical behavior and suggest where fiscal strain may be developing.

The estimates provided here are intended to supply practical interstate comparisons of state-local taxes that conform to a standardized basis. Each state table presents tax capacity data in tabular and chart form. For eight tax categories, the numerical columns provide for each state: (1) its per capita tax capacity for each tax; (2) its per capita tax capacity indexed to the national average for each base; (3) its total capacity for each tax source; (4) its actual collections from each source; (5) its relative tax effort for each tax; (6) the difference between its actual collections and its total capacity for each tax source; and (7) its per capita collections from each tax. The bar charts, for each of seven tax categories, reflect a state's per capita tax capacity, its per capita collections,

and the national per capita tax capacity.

The second set of tables provides breakdowns for each of the 24 taxes used to derive the Representative Tax System estimates. Each table presents detailed information on the distribution of capacity and effort on a state-by-state basis. For each tax, data are presented for each state's (1) tax base for that tax, (2) per capita tax capacity, (3) per capita capacity indexed to the national norm, (4) total capacity, (5) actual collections, (6) tax effort, (7) collections less capacity, and (8) per capita collections.

Two considerations must be noted regarding the use of the Representative Tax System estimates: the indices reported are *approximations* of the measures that could be constructed if perfect, timely data were available. In addition, the comparisons between years are subject to variations in the methodology used by different researchers. The earlier years have been partially revised, but

some differences may be the result of technique and not substance.

The ACIR staff has updated the Representative Tax System not only to satisfy research and public interests, but also because it is a prime candidate for use in federal grant programs. Whatever the theoretical merits of the different approaches to capacity measurement, however, the replacement of the traditional per capita income measure with the tax capacity estimates is bound to be highly controversial because it would create a new set of "winners" and "losers." But aside from this concern, the revisions made in the Representative Tax System methodology in recent years have overcome the system's most serious drawbacks—those of timeliness and complexity—and it has become better understood. When state area capacity measures are considered in grant programs the RTS deserves serious consideration as a replacement for per capita income.

NOTE: All per capita amounts are in dollars; aggregate tax capacity total collections, and collections less capacity are in thousands of dollars. Total tax base is the value of nonfuel mineral production in thousands of dollars.

## Federal Assistance Programs (To Both State and Local Governments) That Use Per Capita Income As An Allocation Factor

PROGRAM NUMBER	PROGRAM NAME	OBLIGATIONS (In thousands of dollars)	
		1979	1980 estimate
10.555	National School Lunch Program	\$2,002,000	\$2,085,900
11.307	Special Economic Development and Adjustment Assistance Program—Long-Term Economic Deterioration	44,832	44,700
13.210	Health Incentive Grants for Comprehensive Public Health Services	—0—	68,000
13.211	Crippled Children's Services	102,100	102,100
13.232	Maternal and Child Health Services	243,400	243,400
13.257	Alcohol Formula Grants	56,800	54,800
13.493	Vocational Education—State Basic Grants	430,266	474,766
13.494	Vocational Education—Consumer and Homemaking	40,929	43,497
13.495	Vocational Education—Program Improvement and Supportive Service	107,688	112,317
13.499	Vocational Education—Special Needs (Special Program for Disadvantaged)	20,000	20,000
13.500	Vocational Education—State Advisory Councils	5,066	6,073
13.269	Drug Abuse Prevention Formula Grants	40,000	38,000
13.624	Rehabilitation Services and Facilities—Basic Support (Basic Support Program)	817,484	817,484
13.630	Development Disabilities—Basic Support and Advocacy Grants	39,118	50,680
13.645	Child Welfare Services—State Grants	56,500	66,150
13.714	Medical Assistance Program (Medicaid)	12,833,967	14,770,896
13.808	Assistance Payments—Maintenance Assistance (State Aid) (AFDC)	6,563,006	7,096,384
14.221	Urban Development Action Grants	615,050	740,548
15.417	Urban Park and Recreation Recovery Program	19,200	77,000

17.235	Senior Community Service Employment Program	\$229,100	\$258,324
21.300	State and Local Government Fiscal Assistance General Revenue Sharing	6,856,000	6,863,000
23.002	Appalachian Supplements to Federal Grant-In-Aid (Community Development)	49,087	63,588
23.004	Appalachian Health Programs	16,295	26,452
23.005	Appalachian Housing Project Planning Loan, Technical Assistance Grant and Site Development and Offsite Improvement Grant: State Appalachian Housing Programs	10,361	12,204
23.010	Appalachian Mine Area Restoration	228	9,317
23.011	Appalachian State Research, Technical Assistance, and Demonstration Projects	10,068	14,980
23.012	Appalachian Vocational and Other Education Facilities and Operations	26,900	16,246
23.013	Appalachian Child Development	9,993	8,291
65.001	Water Resources Planning	3,070	9,630
	Total	<hr/>	<hr/>
		\$ 30,248,488	\$34,194,727

<sup>1</sup> This is the number assigned to the program in the *1980 Catalog of Federal Domestic Assistance*.

*Federal Domestic Assistance*, Washington, DC, 1980; and Dan-uta Emery, et al, *Distributing Federal Funds: The Use of Statistical Data* (Preliminary Report), U.S. Department of Commerce, Office of Statistical Policy and Standards, Washington, DC, 1980.

# Tax Base Definitions, Allocators, And Sources For The 1979 Tax Capacity Estimates

In this appendix, each tax is defined, the tax base allocator is described, and data sources are listed. The tax definitions are those used by Department of Commerce, Bureau of the Census. With few exceptions, all the data on state and local tax collections were supplied by pub-

lications of the Census Bureau: *State Tax Collections in 1979*, *Governmental Finances in 1978-79*, and *State Government Finances in 1979*. Some unpublished data on various tax components were provided by the Census Bureau and state revenue departments.

## 1. General Sales or Gross Receipts Taxes.

### Definition.

Sales or gross receipt taxes which are generally applicable to all types of goods and services. Taxes imposed distinctively upon sales of selected commodities are reported separately under selective sales taxes. West Virginia's sales tax receipts (as reported by the Bureau of the Census) from a "business and occupations" tax on the coal industry were deleted from the sales tax and apportioned to the severance tax.

### Allocator.

General retail sales of retail trade and selected service businesses. This includes all establishments engaged in selling merchandise for personal or household consumption. The service businesses which are included are hotels and motels, amusement and recreation services (including motion pictures), and personal services, such as laundries, and beauty and barber shops.

Excluded from this base allocator are the sales of food and drugs which are commonly tax exempt. Because of data limitations, sales of gasoline have *not* been excluded, although they are usually taxed separately. In general, states have retail sales and gross receipts tax bases that are broader than the one defined here because they cover more transactions, such as public utility sales, wholesale trade, or construction contractors. As a result, the rate used for the Representative Tax System is higher than the actual effective rate.

State-by-state sales of selective service industries for 1979 were estimated by allocating the 1979 national total according to the 1977 state shares adjusted for the change in each state's personal disposable income between 1977 and 1979.

### Sources.

Retail Sales (1979): Sales and Marketing Management, *1980 Survey of Buying Power*, New York, NY, July 1980.

Service Sales (1977): U.S. Department of Commerce, Bureau of the Census, *Census*

*of Business, Selected Services—Area Statistics (1977)*, Washington, DC, 1980.  
Service Sales (1979): U.S. Department of Commerce, Bureau of the Census, *Current Business Reports, Monthly Selected Service Receipts*, Washington, DC, January 1980.  
Disposable Income (1979): U.S. Department of Commerce, Bureau of Economic Analysis, *Survey of Current Business*, Washington, DC, August 1980.

## 2. Selective Service and Gross Receipts Taxes.

Tax levies which are selectively imposed on particular kinds of commodities or businesses.

### 2.A. Motor Fuels.

**Definition.** Selective sales and gross receipts taxes on gasoline, diesel oil, and other fuels used in motor vehicles, including aircraft fuel.

**Allocator.** Total quantity of motor fuel consumed in gallons.

**Source.** U.S. Department of Transportation, Federal Highway Administration, *Motor Fuel Use—1979*, Table MF-21, Washington, DC, 1980.

### 2.B. Alcoholic Beverages.

**Definition.** Selective sales and gross receipts taxes on alcoholic beverages.

**Allocator.** Total volume (in wine gallons) of distilled spirits sold. Although many states also tax beer and wine, the volume of spirits should approximate the pattern of consumption of these other alcoholic beverages. Because distilled spirits are relied upon much more heavily than other beverages for tax revenue, this proxy should not pose serious problems.

**Source.** Distilled Spirits Institute, *Annual Statistical Review 1979*, Washington, DC, 1980.

### 2.C. Tobacco Products.

**Definition.** Selective sales and gross receipts taxes on tobacco products, including related taxes on cigarette tubes and paper, and synthetic cigars and cigarettes.

**Allocator.** Number of packages of cigarettes sold.

**Source.** Tobacco Tax Council, *The Tax Burden on Tobacco*, Vol. 14, 1979, Washington, DC, 1980.

### 2.D. Insurance.

**Definition.** Taxes imposed distinctively on insurance companies and measured by gross premiums or adjusted gross premiums.

**Allocator.** Direct premiums written within states for life, health, property, and liability insurance.

**Sources.** Life Insurance: American Council of Life Insurance, *Life Insurance Fact Book (1980)*, Washington, DC, 1980.  
Health Insurance: Health Insurance Institute, *Source Book of Health Insurance Data, 1980–81*, Washington, DC, 1981.  
Property and Liability Insurance: Insurance Information Institute, *Insurance Facts, 1980–81*, Washington, DC, 1980.

### 2.E. Public Utilities.

**Definition.** Taxes imposed distinctively on public telephone, telegraph, power and light companies, and other public utilities, including local government-owned utilities. These taxes are measured by gross receipts, gross earnings, or units of service sold. Public utility license taxes are also included in this category.

**Allocator.** The sum of all electric, gas, and telephone company gross revenues. Electric and gas revenues are for all publicly owned and private companies. Because telephone revenues for the Bell System and the independent telephone companies are not available on a state-by-state basis, the national total for telephone revenues was allocated to the states according to a weighted average of the number of telephones (22%), the number of local calls (22%), and the number of toll calls (56%).

**Sources.** Gas Utility Revenues: American Gas Association, *Gas Facts—1979*, Arlington, VA, 1980.  
Electric Utility Revenues: Edison Electric Institute, *Advance Release of Data for the 1980 Statistical Yearbook of the Electric Utility Industry*, Washington, DC, 1980.  
Telephone Revenues and Number of Telephones: U.S. Independent Telephone Association, *Independent Telephone Statistics, 1979*, Washington, DC, 1980.  
Number of Local and Number of Toll Calls: Federal Communications Commission, *Statistics of Communications Common Carriers, 1979*, Washington, DC, 1981.

## 2.F. Parimutuels.

**Definition.** Taxes measured by amounts wagered at race tracks, including “breakage” collected by the government.

**Allocator.** Parimutuel turnover from horse and dog racing and jai alai.

**Source.** National Association of State Racing Commissioners, *Parimutuel Racing, 1979*, Lexington, KY, 1980.

## 2.G. Amusements.

**Definition.** Selective sales and gross receipts taxes on admission tickets or admission charges and on gross receipts of all or specified types of amusement businesses. License taxes on amusement businesses are also included.

**Allocator.** Receipts of establishments that provide amusement and entertainment services. Movie theater receipts and casino net revenues are included; gambling receipts for hotels are classified in the general sales tax base because of data availability.

Amusement receipts data for 1979 were derived by allocating that year’s national total according to the 1977 state shares adjusted for the change in each state’s disposable personal income between 1977 and 1979. New Jersey’s share of amusement sales was adjusted to reflect the opening of casinos during the interim years.

**Sources.** Amusement Receipts (1977): U.S. Department of Commerce, Bureau of the Census, *Census of Business, Selected Services—Area Statistics (1977)*, Washington, DC, 1980.

Amusement Receipts (1979): U.S. Department of Commerce, Bureau of the Census, *Current Business Reports, Monthly Selected Service Receipts*, Washington, DC, 1980.

Disposable Income: U.S. Department of Commerce, Bureau of Economic Analysis, *Survey of Current Business*, Washington, DC, August 1980.

## 3. License Taxes.

These are taxes levied as a condition of doing business or nonbusiness privilege. Licensing is usually imposed at a flat rate for either revenue raising or regulation.

### 3.A. Motor Vehicles.

- Definition.** License taxes imposed on owners or operators of motor vehicles for the right to use public highways, including charges for registration, inspection, and vehicle mileage and weight taxes on motor carriers.
- Allocator.** Number of registrations for private and commercial vehicles. This does not differentiate between the much higher rate charged for trucks and buses.
- Source.** U.S. Department of Transportation, Federal Highway Administration, *State Motor Vehicle Registrations—1979*, Table MV-1, Washington, DC, October 1980.

### 3.B. Motor Vehicle Operators.

- Definition.** Licensing for the privilege of driving motor vehicles, including both private and commercial licenses.
- Allocator.** Estimated number of licenses in force.
- Source.** U.S. Department of Transportation, Federal Highway Administration, *Estimated Licensed Drivers, by Sex—1979*, Table DL-1A, Washington, DC, September 1980.

### 3.C. Corporations.

- Definition.** Franchise license taxes, organization, filing, and entrance fees, and all other license taxes which are applicable, with only specified exceptions, to all corporations.
- Allocator.** Number of corporations within a state, including nonprofit corporations.
- Source.** U.S. Department of the Treasury, Commissioner of Internal Revenue, *Annual Report 1979*, Washington, DC, 1980.

### 3.D. Alcoholic Beverages.

- Definition.** License taxes for manufacturing, importing, wholesaling, and retailing alcoholic beverages other than those based on volume, value of transactions, or assessed value of property.
- Allocator.** Number of retail licenses issued for the sale of distilled spirits. Licenses for the exclusive sale of beer and wine are excluded.
- Source.** Distilled Spirits Council, *Annual Statistical Review 1979*, Washington, DC, 1980.

### 3.E. Hunting and Fishing Licenses.

- Definition.** Commercial and noncommercial hunting and fishing licenses and shipping permits.
- Allocator.** Total number of fishing and hunting licenses, tags, permits, and stamps issued.
- Source.** U.S. Department of the Interior, Fish and Wildlife Service News Release, "1979 Hunting and Fishing License Sales Set Record," Washington, DC, June 26, 1980.

## 4. Individual Income Tax.

- Definition.** Taxes on individuals measured by income and taxes distinctively imposed on special types of income (e.g., interest, dividends, intangibles, etc.). Taxes measured by income from intangible property are reported here even though locally designated as "property" taxes.
- The Census includes locally imposed corporate income taxes with local income taxes (instead of with corporate income taxes) and, with the exception of New York,

they are included here. In most jurisdictions these taxes are relatively small. An exception is New York City, where an adjustment was made to allocate local corporate tax receipts to the corporate income tax base.

**Allocator.**

Total federal income tax liability of state residents. This is essentially the total amount of federal income taxes paid by individuals after credits. Because it is prevailing state practice to allow income tax credits for taxes paid to states other than the state of residence, residency adjustments were made to account for both the income taxes collected from nonresidents and credits allocated to residents for taxes paid to non-resident states. State federal income tax liabilities were changed in proportion to the ratio of the BEA residency adjustment to resident personal income.

**Sources.**

Income Tax: U.S. Department of the Treasury, Internal Revenue Service, *Statistics of Income, 1979 Income Tax Returns, Preliminary*, Washington, DC, 1981.  
 Residency Adjustment: U.S. Department of Commerce, Bureau of Economic Analysis, *Survey of Current Business*, Washington, DC, August 1980.

**5. Corporation Income Tax.**

**Definition.**

Taxes on corporations and unincorporated businesses measured by net income.

**Allocator.**

Total federal net income for each of 35 Standard Industrial Classification (SIC) industries was allocated to the states according to the following procedure:

Nationwide net corporate income (1979) was estimated for each of 35 SIC industries by 1977 net income (IRS), adjusted to reflect the change in profits (BEA) for each industry. For each industry, the typical three-factor formula—one-third payroll, one-third property, and one-third sales by destination—should be used to allocate each industry's national income to the states. However, data for corporate property and sales by state are not available and proxies had to be used to estimate these factors in the formula for each industry. Payroll data, by industry, by state, are available and formed the basis for the proxies which were utilized.

For the property factor of the formula, property was assumed to be distributed in an identical fashion as payroll. Hence, the payroll factor was used to proxy for property, double-weighting payroll in the formula.

Because corporate sales by destination are unlikely to mirror either payroll or retail sales, neither of these proxies was used to estimate the sales factor in the formula. Instead, through use of payroll breakdowns by industry, by state, and a national input-output table, a proxy for sales was derived according to the following procedure:

Let:

$X(i,c)$  = The percentage of the dollar value of industry  $i$ 's output that is commodity  $c$ .

$Y(c,j)$  = The percentage of the total dollar value of commodity  $c$  used as an input in industry  $j$ . Where  $c$  is not used as an intermediate input, but is purchased by consumers, "personal consumption expenditures" constitutes the relevant industry.

$$\text{Then: } \sum_{c=1}^{36} [X(i,c)*Y(c,j)] = A(i,j)$$

Where  $A(i,j)$  = the percentage of industry  $i$ 's output purchased by industry  $j$ . When  $j$  is personal consumption expenditures,  $A(i,j)$  = the amount of industry  $i$ 's output sold as final goods.

Now Let:

$S(w,j)$  = the percentage of industry  $j$ 's payroll located in state  $w$ . Where industry  $j$  is personal consumption expenditures, let  $j$  equal state  $w$ 's share of total national retail sales.

$$\text{Then } \sum_{j=1}^{36} [S(w,j) * A(i,j)] = K(w,i)$$

Where  $K(w,i)$  = the share of industry  $i$ 's output sold in state  $w$

Thus,  $K(w,i)$  is used to proxy for the sales-by-destination factor in the three-factor formula.

The three-factor formula is applied to the estimated total income for each industry (from above) to determine each state's income apportionment and summed over all industries to derive each state's total corporate income tax base.

Let:  $I(i)$  = Total income for industry  $i$

$$\begin{aligned} \text{Then: } I(w,i) &= I(i) * [(1/3) * K(w,i)] * [(2/3) * S(w,i)] \\ &= \text{The income of industry } i \text{ apportioned to state } w. \end{aligned}$$

$$\begin{aligned} \text{And: } I(w) &= \sum_{i=1}^{36} I(w,i) \\ &= \text{The total corporate income for all industries allocated to state } w. \end{aligned}$$

**6. Property Taxes.** The property tax is separated into five different components—residential, commercial, farm, public utilities, and vacant land—each of which is estimated individually. The allocation of property taxes among the various classes of property are approximations based on assessed values for 1976. The Census Bureau does not provide a breakdown of property tax payments by class of property. Special state taxes on other classifications of property and state and/or local taxes on household personal property have been excluded where possible.

### 6.A. Residential Property.

#### Definition.

Taxes conditioned on ownership of single-family houses, not on farms, and on multifamily residences excluding motels and hotels. Residential property tax rates are applied to the combined value of buildings and land.

The residential share of the property tax burden was estimated by the residential share of assessed property values in 1976. This share was applied to 1979 property tax collections, after the deletion of farm, personal household, and special state property taxes, to derive residential property tax receipts.

#### Allocator.

Estimated residential property values for single and multifamily residences.

Property values for 1979 were estimated by extrapolating the estimated market value

of each state's residential property (1976) by the change in the average purchase prices of single-family dwellings between 1975-76 and 1978-79. The two-year basis for the ratio was utilized in order to reduce variations that might have arisen from differing compositions of home sales.

To the estimated market value of residential property (1979), the value of newly constructed housing between 1976 and 1978 was added. This was derived by summing the value of construction permits issued for the three years, and then inflating the total to reflect the value of the associated land.

### **6.B. Commercial and Industrial Property.**

#### **Definition.**

Taxes conditioned upon the ownership of commercial and industrial property (excluding public utilities) based on the value of land, buildings and equipment, inventories, and depletable assets representing the value of mineral property, oil and gas wells, other natural deposits, standing timber, etc.

The tax burden on business property was derived by applying the percentage of 1976 gross assessed value of business property to the total of 1979 total property tax collections. Because business property includes utility companies, as well as commercial-industrial property, the commercial-industrial share of business property taxes was determined by taking the ratio of the book value of corporate (exclusive of utility) assets to the book value of corporate-plus-utility assets.

#### **Allocator.**

Estimated net book value of assets, including inventories, depreciable assets, depletable assets, and land of corporations. Property values for partnerships and other nonincorporated business, farms, and public utilities are not included; railroad property is included.

Net book values for 35 SIC industry groupings for 1979 were estimated by applying to the 1976 values (IRS), the change between 1976 and 1979 in net book values of property assets (FTC). Because Federal Trade Commission data are not available for transportation, finance, or service industries, their book values were inflated by the changes in their respective total payrolls between 1976 and 1979. The estimated corporate property values for each industry were allocated to the states according to each state's share of each industry's payroll. The sum of all of the individual industry property values was used as an estimate of each state's commercial-industrial property tax base.

Special adjustments were made to the assets of corporations in the coal mining, and oil and gas extraction industries because they are primarily captives of corporations which are involved in other industries. The assets of the coal mining industry were

increased to reflect the ownership of coal companies by petroleum refining, steel, and utility companies. Similarly, the assets of the oil and gas extraction industry were inflated to account for their ownership by petroleum refiners. Conversely, the assets of the parent organizations were decreased by the asset amounts that were added to the coal mining, and oil and gas extraction industries.

Payroll by Industry, by State: U.S. Department of Commerce, Bureau of Economic Analysis, *Survey of Current Business*, Washington, DC, August 1980.

**6.C. Farm Real Estate.**

**Definition.**

Taxes conditioned on the ownership of farm realty and farm personal property, such as livestock, crop inventories, and farm equipment.

**Allocator.**

Estimated value of farmland and buildings.

**Sources.**

Farm Values: U.S. Department of Commerce, Bureau of the Census, *Statistical Abstract of the United States, 1979*, Table #1191, Washington, DC, 1980.  
Farm Property Taxes: U.S. Department of Agriculture, Economics and Statistics Service, *Agricultural Statistics, 1981*, Washington, DC, 1981.

**6.D. Public Utilities.**

**Definition.**

Taxes conditioned on investor ownership of public utilities such as gas, electric, and telephone companies. Public utility property tax rates are applied to the combined value of buildings, equipment, material, and land.

**Allocator.**

Because individual state data are not available, each state's public utility property tax base was based on a proxy measure that consisted of the sum of gas, electric, and telephone company nonfinancial assets, estimated by the following:

1. Gas company net assets were allocated to the each state according to its share of the total number of miles of gas pipeline.
2. Electric company net assets were allocated to each state according to its share of the total investor-owned electrical generating capacity.
3. Telephone company net assets were allocated to each state according to its share of the total number of telephones.

Independent Telephone Company Net Assets and Number of Telephones: U.S. Independent Telephone Association, *Independent Telephone Statistics (1979)*, Washington, DC, 1980.

## 6.E. Vacant Land.

- Definition.** Taxes imposed upon the owners of vacant lots and open space not utilized for farming.
- Allocator.** Market values for 1976 were inflated by the percentage change in single-family home prices between 1975-76 and 1978-79. The value of vacant land is likely to track fairly closely to the value of dwellings because land prices reflect the same relative scarcity that existing housing prices indicate.
- Sources.** Vacant Land Values: U.S. Department of Commerce, Bureau of the Census, *1977 Census of Governments, Taxable Property Values and Assessment/Sales Price Ratios*, Washington, DC, 1978.

## 7. Death and Gift Taxes.

- Definition.** Taxes imposed on the transfer of property at death, in contemplation of death, or as a gift.
- Allocator.** Value of taxable estates for 1976.
- Source.** U.S. Department of the Treasury, Internal Revenue Service, *Statistics of Income, 1976 Estate Tax Returns*, Washington, DC, 1979.

## 8. Severance Taxes.

- Definition.** Taxes imposed distinctively on the removal of natural resource products—e.g., oil, gas, and other minerals. The Alaskan special tax on pipeline property and the state's unique oil and gas corporate income tax have been included, as has West Virginia's business tax on coal companies. Taxes imposed on resources other than minerals, such as water, timber, or fish, have been excluded. Because oil and gas, coal, and nonfuel minerals are taxed at substantially different rates, each was estimated individually—separate representative tax rates and bases were measured for three severance subcategories.
- Allocator.** For each subcategory—oil and gas, coal, and nonfuel minerals—the base was estimated by the value of production.
- Sources.** Value of Mineral Production, except fuels: U.S. Department of the Interior, Bureau of Mines, *Minerals Yearbook, 1978-79*, Preprint, Washington, DC, 1981.  
Value of Oil Production: U.S. Department of Energy, Energy Information Administration, *Energy Data Reports, Petroleum Statement, Annual*, Washington, DC, 1981.

The reports of the Advisory Commission on Intergovernmental Relations are released in three series: the "A" series denotes reports containing Commission recommendations; the "M" series contains information reports; and the "S" series identifies reports based on public opinion surveys. All Commission reports are printed by, and available from the U.S. Government Printing Office, Washington, DC.

# What is ACIR?

The Advisory Commission on Intergovernmental Relations (ACIR) was created by the Congress in 1959 to monitor the operation of the American federal system and to recommend improvements. ACIR is a permanent national bipartisan body representing the executive and legislative branches of Federal, state, and local government and the public.

The Commission is composed of 26 members—nine representing the Federal government, 14 representing state and local government, and three representing the public. The President appoints 20—three private citizens and three Federal executive officials directly and four governors, three state legislators, four mayors, and three elected county officials from slates nominated by the National Governors' Conference, the Council of State Governments, the National League of Cities, U.S. Conference of Mayors, and the National Association of Counties. The three Senators are chosen by the President of the Senate and the three Congressmen by the Speaker of the House.

Each Commission member serves a two year term and may be reappointed.

As a continuing body, the Commission approaches its work by addressing itself to specific issues and problems, the resolution of which would produce improved cooperation among the levels of government and more effective functioning of the federal system. In addition to dealing with the all important functional and structural relationships among the various governments, the Commission has also extensively studied critical stresses currently being placed on traditional governmental taxing practices. One of the long range efforts of the Commission has been to seek ways to improve Federal, state and local governmental taxing practices and policies to achieve equitable allocation of resources, increased efficiency in collection and administration, and reduced compliance burdens upon the taxpayers.

Studies undertaken by the Commission have dealt with subjects as diverse as transportation and as specific as state taxation of out-of-state depositories; as wide ranging as substate regionalism to the more specialized issue of local revenue diversification. In selecting items for the work program, the Commission considers the relative importance and urgency of the problem, its manageability from the point of view of finances and staff available to ACIR and the extent to which the Commission can make a fruitful contribution toward the solution of the problem.

After selecting specific intergovernmental issues for investigation, ACIR follows a multistep procedure that assures review and comment by representatives of all points of view, all affected levels of government, technical experts, and interested groups. The Commission then debates each issue and formulates its policy position. Commission findings and recommendations are published and draft bills and executive orders developed to assist in implementing ACIR policies.
